SOLITARY CIRCUMSCRIBED LESIONS OF THE LUNG

STUDY OF 156 CASES IN WHICH RESECTION WAS PERFORMED

Robert T. Hood Jr., M.D., C. Allen Good, M.D., O. Theron Clagett, M.D.
and
John R. McDonald, M.D., Rochester, Minn.

The importance of a solitary circumscribed mass in the lung has attracted increasing recognition in recent years. As a result of the extended use of roentgenologic examination of the chest, detection of these lesions is now commonplace. Advances in thoracic surgery have resulted in an effective means of definitively managing these lesions. As a consequence, complacency is no longer justifiable on the part of an attending physician who discovers such a lesion with its recognized malignant potentiality.

Circumscribed mass lesions of the lung are generally peripheral in location with respect to the pulmonary hilus. Because of this, important clinical problems in management and diagnosis arise. In the first place, symptoms develop less commonly and at a later stage than those caused by lesions lying close to a central bronchus. Consequently, it is more difficult to impress on the patient the importance of assuming an active approach toward the management of these frequently asymptomatic lesions. Second, the peripheral location of the lesion renders it inaccessible to direct bronchoscopic visualization and frequently reduces the tendency for the production of sputum containing exfoliated cells or significant organisms. For these reasons, important diagnostic aids available for the study of most diseases of the chest are ineffective for the investigation of solitary circumscribed lesions. The problem confronting the clinician is, therefore, a complex one. On the one hand, the possibility is ever present that the rounded shadow may represent a malignant process in a relatively early and operable stage. On the other hand, recourse to exploratory operation should never supplant simpler, less hazardous diagnostic measures. What then should be the clinician's policy with regard to these lesions? What diagnostic procedures are indicated? To what extent should preoperative diagnostic studies be pursued? What clinical features of a circumscribed mass increase the suspicion of malignancy? Finally, under what circumstances should exploratory thoracotomy be advised?

Answers to these questions can be obtained only by a comprehensive study of a large and varied group of solitary mass lesions of the lung. In an attempt to formulate a working policy applicable to all patients with such lesions, the material available to us at the Mayo Clinic has been reviewed in detail. All cases of surgically removed solitary circumscribed lesions without regard to size, status of preoperative diagnosis, or presence of respiratory symptoms constitute the basis of this study. It is our feeling that a true evaluation of various diagnostic procedures and a sound basis for dependable advice regarding operation can best be obtained from the study of all circumscribed lesions rather than by a study of a limited group of them restricted as to preoperative diagnosis, size, or symptomatology.

MATERIAL AND METHOD OF STUDY

The records of the cases for this study were obtained from the files of the Mayo Clinic after the chest roentgenograms of the 1,355 patients who underwent pulmonary resection during the period January, 1940, through June 30, 1951, were reviewed. Only those cases in which actual excision of the entire mass was carried out were studied, since only those cases provided complete pathological material for adequate study. Cases were selected solely on the basis of the roentgenographic appearance of the lesion. For qualification of a lesion as a circumscribed mass it had to possess the following characteristics. 1. It had to appear to be situated in the substance of the lung. 2. It had to constitute the only significant pathological change in the pulmonary fields. 3. It could not be associated with obstructive changes in the lung peripheral to the mass. 4. It could not display cavitation.

The size of the lesion, the sharpness and regularity of outline, the position in the pulmonary field, and the presence or absence of calcium were not factors determining the selection. While many authorities have observed more rigid qualifications for circumscribed lesions than these, the establishment of such qualifications necessarily in-

---

From the Mayo Clinic.

volves the use of arbitrarily set limits, and the wisdom and practicality of such selection is a matter of considerable doubt.

Naturally, with the inclusion of such a wide diversity of lesions, the appearance of the roentgenographic shadows varied greatly. The smallest shadows represented both benign and malignant lesions, as did the large shadows. Between these extremes in size, all gradations of size and a wide variety of shapes, densities, and sharpness of outline were encountered.

The records of these patients were reviewed in detail. Particular attention was directed toward the history of previous pulmonary disease and other systemic disease capable of producing pulmonary manifestations. The laboratory examinations carried out on these patients were studied to determine their diagnostic worth in evaluating the pulmonary lesion. These examinations included specific diagnostic procedures, such as the cytological and bacteriological examination of the sputum and bronchial washings. The findings obtained by bronchoscopic examination were studied critically. The pathological findings at the time of operation and the indications for the various operative procedures were reviewed. Microscopic sections from the excised tissue were reexamined to confirm the original diagnosis. Many of the tissues were studied bacteriologically, and the results of these studies were available for this review. Based on the definitive diagnosis established in the surgical, pathological, and bacteriological laboratories, the information obtained from the various preoperative studies was finally evaluated in an attempt to formulate a working policy for the clinical investigative management of these patients.

TABLE 1.—*Pathological Classification of Solitary Circumscribed Lesions of the Lung*

Lesion	Cases		%	
Malignant neoplasms				
Bronchogenic carcinoma	25		16	
Bronchial adenoma	12		7.7	
Fibrosarcoma	1		0.6	
Metastatic malignant lesion	17		10.9	
Total		55		35.3
Benign neoplasms				
Hamartoma	25		16	
Mesothelioma	3		1.9	
Thymoma	1		0.6	
Hemangioma	1		0.6	
Inflammatory				
Granuloma	65		41.7	
Chronic pneumonitis	1		0.6	
Chronic abscess	1		0.6	
Miscellaneous				
Bronchial cyst	4		2.6	
Total		101		64.7
Total	156			

PATHOLOGICAL AND BACTERIOLOGICAL FEATURES

The distribution of the cases according to the pathological classification of the lesion is summarized in table 1. In 85 cases (about 54%), the shadow represented a neoplastic process, while, in 67 cases (nearly 43%), the lesion resulted from inflammation. In the remaining cases, a bronchial cyst was found. The commonest neoplastic lesion was bronchogenic carcinoma; this was encountered in 16% of the total series. Twelve of the lesions (7.7%) were adenomas of the bronchus. Hamartomas were encountered in 25 cases, a frequency similar to that of bronchogenic carcinoma. Metastatic lesions, including carcinomas and sarcomas, were responsible for 10.9% of the lesions. Three of the solitary lesions were mesotheliomas. Of the two remaining neoplastic lesions, one was a hemangioma, and the other presented microscopic evidence suggestive of an intrapulmonary thymoma.

The incidence of malignancy among the neoplastic lesions was impressive. Nearly 65% of the neoplastic nodules, approximately 35% of the lesions in the entire group of cases, were malignant. Because of the recognized potentiality of bronchial adenoma to metastasize, this lesion was included in the malignant group.

With two exceptions, the inflammatory lesions presented the microscopic picture of a granulomatous process. In the granuloma group, there were cases in which the causative agent was bacteriological, mycotic, or chemical in nature or in which the cause was an irritant, the specific nature of which remained undetermined. The term "tuberculoma" was not applied to any group of these granulomatous lesions, since the exact incidence of tuberculomas remains a matter for speculation. Lesions from which the tubercle bacillus are isolated are undoubtedly tuberculomas in the true sense of the word but, most likely, a large proportion of the group of indeterminate granulomas represents processes caused by the same agent that has since lost its demonstrable viability. Thus, to limit the application of the term "tuberculoma" to the bacteriologically active group of lesions would be misleading, just as its application to the total group of granulomas would be without basis.

The lesions in the remaining four cases were bronchial cysts. The difficulty of accurately determining the precise nature, whether developmental or inflammatory, of these lesions led to their classification as a miscellaneous group.

Pathological examination of the excised tissue was made by the frozen tissue technique immediately after the tissue was received in the laboratory. Confirmation of the diagnosis was established on the following day by examination of the fixed tissue sections. The one limitation that was applied equally to the pathological examination of both the fixed and the frozen tissues was the inability of the pathologist to determine the precise causative basis for the granulomatous lesions. For this reason, bacteriological studies were performed on excised tissue in most cases of granulomatous lesions.

Fifty-three of the 65 granulomatous lesions were examined bacteriologically, and pathological organisms were isolated in 11. The commonest organism was the tubercle bacillus, which was found in seven cases. Coccidioides immitis was isolated in three cases and Brucella suis in one case. The lesions from which these organisms were isolated all showed histological evidence of tissue activity; however, by no means did all the histologically active lesions yield a pathological organism after bacteriological study.

The histological picture in two of the lesions was that of a lipoid granuloma. Further chemical studies of the tissue in these cases revealed the irritant to be liquid petrolatum in one case and oil from an endogenous source in the other.

AGE AND SEX

The youngest patient in this study was 6 years of age and the oldest was 69 (table 2). As would be anticipated, patients with bronchogenic carcinoma were older than those in the other large groups. The youngest patient with bronchogenic carcinoma was 36 years of age, and more of the patients with this lesion were in the age group from 51 to 60 years than in any other decade. Patients with bronchial adenoma had a similar age distribution. Hamartomas were encountered in patients of all age groups, the largest number being in the group between 51 and 60 years. This is not to be construed as evidence that a hamartoma is most commonly present in persons in this decade of life; rather, it reflects the greater number of examinations carried out on patients of this age group. Various metastatic lesions were found in patients of all age groups; the age characteristic of the primary lesion, of course, was the determining factor. While granulomas were removed from patients of all ages, the greatest number was found in the age group from 41 to 50 years. Undoubtedly, as was the case with the group with hamartoma, the greater number of exploratory thoracotomies performed in this age group had an important bearing on the fact that there were more patients with granuloma in this age group than in any other. Typically, bronchial cysts are discovered and removed during young adult life, the oldest patient in this series being 42 years of age.

TABLE 2.—*Distribution of Solitary Circumscribed Lesions of the Lung According to Sex and Age of Patients*

	Cases								
				Age, Years					
Lesion	Total	Men	Women	1 to 30	31 to 40	41 to 50	51 to 60	61 to 70	Range
Bronchogenic carcinoma	25	20	5	..	1	5	10	9	36 to 66
Bronchial adenoma	12	7	5	..	3	2	4	3	37 to 69
Fibrosarcoma	1	1	..	..	..	1	..	..	41
Metastatic malignant lesion	17	7	10	3	3	4	5	2	6 to 67
Hamartoma	25	18	7	2	5	5	10	3	17 to 66
Mesothelioma	3	3	..	..	..	..	2	1	54 to 64
Thymoma	1	..	1	..	..	..	..	1	65
Hemangioma	1	..	1	..	..	..	..	1	65
Granuloma	65	29	36	4	14	25	16	6	18 to 66
Chronic pneumonitis	1	1	..	..	..	..	1	..	54
Chronic abscess	1	1	..	..	..	1	..	..	42
Bronchogenic cyst	4	2	2	1	2	1	..	..	26 to 42
Total	156	89	67	10	28	44	48	26	

TABLE 3.—*Symptoms Associated with Solitary Circumscribed Lesions of the Lung*

	Cases							
Lesion	Total	No Symptoms Present	Cough	Sputum	Pain	Fever	Wheeze	Hemoptysis
Bronchogenic carcinoma	25	7	16	16	10	7	2	8
Bronchial adenoma	12	4	8	7	4	1	1	4
Fibrosarcoma	1	..	1	1	..	..	..	..
Metastatic malignant lesion	17	11	3	2	2	..	..	3
Hamartoma	25	21	3	1	1	..	..	..
Mesothelioma	3	1	1	1	..	1	1	..
Thymoma	1	..	1	..	1	..	..	..
Hemangioma	1	..	1	1	..	..	..	..
Granuloma	65	36	21	11	12	6	..	..
Chronic pneumonitis	1	..	1	1	1	..	..	1
Chronic abscess	1	..	..	..	1	1	..	..
Bronchogenic cyst	4	1	2	2	..	..	..	2

The sex distribution was characteristic of the specific disease process. Of the entire group, 57% were men. Of the malignant lesions, 64% were found in men; 80% of the bronchogenic carcinomas, 58% of the bronchial adenomas, and 41% of the metastatic lesions were found in men. Granulomas were encountered with similar frequency in both men and women.

SYMPTOMS

While in the study of solitary pulmonary lesions an important distinction has frequently been made between symptomatic and asymptomatic lesions, such a distinction is often difficult to establish owing to the variable emphasis different patients ascribe to symptoms. Consequently, in this study, the presence or absence of symptoms was not a selective factor, and the symptoms were evaluated relative to the etiological basis of the mass.

In general, patients with primary malignant pulmonary disease were most likely to complain of symptoms. Only 28% of the patients with bronchogenic carcinoma and 33% of those with bronchial adenoma were asymptomatic (table 3). Eighty-four per cent of those with hamartomas, 55% of those with granulomas, and 65% of those with metastatic growths presented no symptoms. Cough was a symptom of importance; it was present in 64% of the patients with bronchogenic carcinoma and 67% of those with bronchial adenoma but occurred in only 32% of those with granulomas.

The presence of sputum likewise was highly important and was encountered in 64% of the patients with bronchogenic carcinoma and in 58% of those with bronchial adenoma but in only 17% of those with granuloma. Pain, though frequently difficult to assess, was most commonly encountered in the group of patients with bronchogenic carcinoma. It did not necessarily signify pleural involvement of the tumor. Fever was the complaint most commonly elicited from the patients with bronchogenic carcinoma. A history of wheeze is always highly significant in any patient presenting a mass in the chest. Because of the peripheral location of the great majority of these lesions, this symptom was not a common complaint. It was reported in two of the patients with bronchogenic carcinoma and in one of the patients with bronchial adenoma. In one instance, a patient with a large mesothelioma complained of wheezing.

The single most important symptom signifying serious disease was hemoptysis. None of the 65 patients with granulomas gave a history of hemoptysis. Thirty-two per cent of the patients with bronchogenic carcinoma and 33% of those with bronchial adenoma had coughed up blood at some time. In fact, with the exception of the patient with chronic pneumonitis and two patients with bronchogenic cysts, a history of hemoptysis signified a malignant pulmonary growth.

HISTORY OF PREVIOUS PULMONARY DISEASE

A rounded pulmonary lesion may be related to a previous morbid process in the lung. The shadow may represent the persisting residuum of a more extensive inflammatory process in which pathological activity has been greatly reduced or has disappeared. The shadow may be indicative of a mass that intermittently obstructs an air passage to produce the well-established picture of obstructive pneumonitis or one of its variants, represented clinically as recurrent pneumonia. It would appear essential, therefore, to inquire carefully into the patient's history in order to elicit evidence of previous bouts of pulmonary infection regardless of the presence of symptoms at the time of the current examination.

The histories of our patients were carefully reviewed to determine to what extent the presence of previous pulmonary disease was of diagnostic value in evaluating the nature of the present pulmonary shadow. Except in a few isolated instances, little aid was derived from this search, and only occasionally did the history of previous pulmonary disease arouse a suspicion of the nature of the underlying process.

Of the 25 patients with bronchogenic carcinoma, only 2 gave histories of pneumonia in the recent past. Three others had experienced pleurisy in the remote past, but it is difficult to see how this could have been related to the current process. This incidence of pulmonary inflammatory disease associated with bronchogenic carcinoma is, of course, much less than that usually found, since these lesions were for the most part peripheral and nonobstructing. In two of the patients, a diagnosis of tuberculosis had been made because a rounded mass was found in the lung, and they had been sent to sanatoriums. One of these patients faithfully followed a program of strict rest in bed for a period of two years, in spite of repeatedly negative results on examination of the sputum for tubercle bacilli. This only serves to emphasize the great and frequently unwarranted responsibility a physician must assume in persisting in the diagnosis of tuberculosis in the absence of confirmatory laboratory data. In this study, these were the only patients of the entire group who actually received treatment in a sanatorium at any time.

Two of the patients with bronchial adenomas had recently experienced bouts of pulmonary infection diagnosed as pneumonia. In both cases, the location of the adenoma could readily have allowed obstruction of the airway to the distal part of the lung.

The history of previous pulmonary disease provided little clinical suggestion of the nature of the granulomatous lesions. In spite of the known association of tuberculosis with granulomatous pulmonary lesions, only 3 of these 65 patients gave even a dubious history of tuberculosis. Two patients had been informed that they had healed tuberculosis, and one patient had been suspected of having tuberculosis at an early age. Six patients had had pleurisy and three others pneumonia at some time, but the relationship between these illnesses and the finding of the pulmonary shadow appeared too remote to be of definite significance.

Among the patients with lesions resulting from other causes, the history of previous pulmonary disease was similar to that which might be obtained from any group of persons of similar age.

HISTORY OF PREVIOUS MALIGNANT DISEASE

A history of previous or simultaneous malignant disease is always strongly suggestive of the nature of a circumscribed intrapulmonary lesion. In this study, there were 19 instances in which the pulmonary lesion appeared in a person who had previously had a malignant tumor removed from an organ other than the lung. In all 19, the pulmonary lesion was presumed to represent metastasis; however, in two instances, the pulmonary shadow was caused by a mass that was totally unrelated to the previously excised growth. In the first case, the patient had undergone two previous resections of the colon for two independent primary adenocarcinomas, the first in 1922 and the second in 1948. During the examination prior to the second operation, a pulmonary mass was detected on the roentgenogram of the chest and was assumed to represent metastasis. Accordingly, resection of the colon was considered as being palliative; however, three years later, this mass had grown only slightly, and no other evidence of metastasis had appeared. For this reason, it appeared justifiable to proceed with resection for this presumably solitary metastatic lesion. Pathological examination of the pulmonary mass revealed it to be a bronchial adenoma. There was no evidence of any metastatic growth elsewhere in the resected specimen. In the second case, a carcinoma of the descending colon was detected during the same examination at which the patient was found to have a solitary lesion in the lung. After resection for the adenocarcinoma of the colon, exploratory thoracotomy was carried out for the resection of the presumably solitary pulmonary metastatic growth. This growth, however, proved to be a hamartoma.

By and large, the finding of a pulmonary mass on the roentgenogram of the chest of a person with known malignant disease elsewhere in the body may be assumed, in most cases, to represent metastasis from the primary growth. It is not within the province of this paper to urge that resection be performed for all such masses; however, the suspicion that the mass may be totally unrelated to the known malignant process must be constantly entertained until proved otherwise. Furthermore, the lack of evident growth of the mass or the failure of the appearance of other nodules in the lungs increases the urgency for proving the nature of the pulmonary mass.

LABORATORY STUDIES

Blood Cell Counts.—A depression of the erythrocyte count or an elevation of the leukocyte count was rarely reported in this group of patients. This is not surprising in view of the fact that the lesions, for the most part, were small and not associated with significant degrees of acute inflammatory change.

Sedimentation Rate.—Elevation of the sedimentation rate of the erythrocytes, in a patient with a solitary lesion in the lung, is of serious significance. Among the patients with bronchogenic carcinomas, 74% of those in whom the sedimentation rate was measured had increased values. On the other hand, only 23% of those who had granulomatous lesions and who had determinations of the sedimentation rate demonstrated increased values. The sedimentation rate was elevated in 50% of the patients with bronchial adenomas and in 55% of those with metastatic pulmonary lesions. Thus, the frequent finding of an elevation of the sedimentation rate among the patients with neoplastic lesions demonstrates the important place of this test in the clinical evaluation of patients with circumscribed lesions of the lung.

Skin Tests.—In the clinical evaluation of solitary pulmonary lesions, the importance of the tuberculin test resides primarily in its reaction being negative. This concept is based on the assumption that most granulomatous lesions are tuberculous in origin. In two groups of patients, one group with solitary neoplastic lesions and the other with solitary granulomatous lesions, the incidence of a positive tuberculin reaction should be almost 100% in the second group and no greater in the first group than in the general population of the same age. These assumptions were not substantiated by the findings of this study. Actually the incidence of negative tuberculin reactions was similar (22%) among patients with a granulomatous lesion and patients with bronchogenic carcinoma. For this reason, the report of a negative tuberculin reaction should not in itself influence the clinician's judgment of the nature of the lesion.

Granulomatous lesions are by no means all tuberculous in origin. Important evidence favoring the nontuberculous basis of many of these lesions was obtained by means of skin tests. As stated, in seven cases (22%), the reaction was negative. In 7 out of 10 patients tested for histoplasmin sensitivity, the reaction was positive. Three of these patients were among those who reacted negatively to tuberculin. Reaction to the coccidioidin test was positive in 2 of the 10 persons in whom the test was performed. One patient whose lesion produced a pure culture of Brucella suis gave a positive skin reaction to the antigen of the same organism.

Bacteriological Examination of Sputum. — Sputum was examined for the presence of acid-fast organisms in 31 persons in whom the lesion was of a granulomatous nature, and in none was an acid-fast organism detected. On five occasions, acid-fast organisms were isolated from the excised lesion even though adequate examination of the sputum had failed to detect its presence. Bacteriological examination of sputum appears to be of little value in determining either the nature of the lesion or the presence of bacteriological activity of the lesion, if it is proved to be granulomatous in nature.

Cytological Examination of Sputum and Bronchial Washings.—The value of cytological examination of the sputum in this study appeared indisputable. No false positive results were reported. The sputum was examined for the presence of malignant cells in 15 of the cases of bronchogenic carcinoma and, in 8 (53%) of these, such cells were found (table 4). The bronchial washings in one additional case contained malignant cells. Because many of the patients included in this study were operated on prior to the development of cytological methods for the examination of sputum, this test was not universally employed. As noted in table 4, the incidence of positive results of examination of the sputum for malignant cells was particularly high among patients with the squamous cell variety of bronchogenic carcinoma. The high reliability of this test should encourage its employment wherever practical. It is the most useful laboratory means available for the establishment of a positive preoperative diagnosis in patients with circumscribed lesions of the lung.

TABLE 4.—*Types of Cells Found on Cytological Examination of Sputum of Patients with Bronchogenic Carcinoma*

	Cases			
Cell Type	Total	Positive	Negative	Not Examined
Squamous cell	6	3	1	2
Small cell	2	0	1	1
Large cell	13	4	3	6
Adenocarcinoma	4	1	2	1
Total	25	8	7	10

BRONCHOSCOPIC EXAMINATION

Bronchoscopic examination was performed in 67 cases. This included 18 cases of bronchogenic carcinoma, 8 of adenoma, 4 of metastatic lesions, 10 of hamartoma, 22 of granuloma, and 5 of various benign conditions. In two patients with bronchogenic carcinoma, a mass was visualized, but biopsy of this tissue revealed only inflammatory changes. In another, a biopsy specimen taken from the region of the right upper lobe bronchus contained malignant tissue, although a mass was not seen. Positive results of bronchoscopic biopsy were obtained in two other cases; bronchial adenoma was disclosed in one case and metastatic malignant disease in the other. In 38 additional cases, biopsy of the bronchial mucosa demonstrated no abnormality. The information gained from bronchoscopic examination and biopsy was extremely meager, so meager that the wisdom of subjecting all patients with circumscribed lesions to routine bronchoscopic examination is seriously questioned. Actually, little should be expected from bronchoscopic examination because of the peripheral position of most of these lesions in the pulmonary fields.

ROENTGENOLOGIC CHARACTERISTICS

A detailed roentgenologic study was made of all available chest roentgenograms of the patients in this series. The results of this study constitute the basis of another publication [1] and will only be summarized here.

Evidence of growth of a pulmonary lesion increased the suspicion of malignancy. Increase in size, however, was encountered in some cases of hamartoma and granuloma and, so, was not invariably indicative of a malignant neoplasm. The location of the pulmonary shadow gave no clue to its cause. In spite of the facts that granulomas are most commonly of tuberculous origin and that tuberculosis notoriously attacks the upper lobes, the circumscribed granulomas were less commonly found in the upper than in the lower lobes.

Benign and malignant lesions, alike, occurred in all sizes. No bronchogenic carcinoma was found that measured less than 2 cm. in diameter, although several of the metastatic lesions were this small. On the other hand, 60% of the granulomas were 2.5 cm. or less in diameter. The large shadows most frequently represented malignant lesions, although large hamartomas and granulomas were encountered.

Table 5.—*Operative Procedures and Hospital Mortality in Patients with Solitary Circumscribed Lesions of the Lung*

	Cases					
Lesion	Total	Local Excision	Segmental Resection	Lobectomy	Pneumonectomy	Deaths
Bronchogenic carcinoma.........	25	0	0	10	15	1 *
Bronchial adenoma..............	12	0	0	12	0	0

Chronic abscess................	1	0	0	1	0	0
Bronchogenic cyst..............	4	0	1	3	0	0
Total..........................	156	60	9	69	18	2

* Death followed lobectomy.

Evidence of calcification, as manifested by punctate densities or concentric lamination, was encountered in 32% of the granulomas and in 28% of the hamartomas but in no other lesions. Lamination was found exclusively in the granulomatous group. Calcification constituted the only roentgenologic assurance of benignancy. Because of the helpfulness of body-section roentgenography in detecting calcification, we feel that it should be more widely employed.

In the group of lesions without visible calcification, the incidence of the various types was somewhat different from that in the entire group. In this calcium-free group, 20% of the lesions were bronchogenic carcinomas, 8% bronchial adenomas, and 14% metastatic malignant lesions. The incidence of malignancy in circumscribed lesions of the lung that did not display calcification was 42%.

A careful examination of features such as sharpness of border, regularity of outline, and density of the mass failed to reveal characteristics useful in distinguishing benign from malignant lesions.

OPERATIVE TREATMENT

All patients in this study underwent surgical excision of the entire lesion (table 5). No cases in which the surgical procedure was limited to a biopsy of the lesion were included in our series. In 101 of the cases, exploratory thoracotomy was the means of diagnosis as well as the means of treatment of the lesion.

The patients with bronchogenic carcinoma were treated by lobectomy in 10 cases and pneumonectomy in 15 cases. There was one death in this group. All patients with bronchial adenoma underwent lobectomy. Hamartomas were removed by local excision in most cases, although, in five, the lesion was excised by lobectomy and, in two, by pneumonectomy. The latter two patients were treated during the period prior to our full understanding of this lesion, and it appears likely that a less taxing operation would be performed in such instances today. Metastatic lesions were removed by lobectomy, as a rule, although one required pneumonectomy, and one was treated by local excision and another by segmental resection. Granulomas were excised locally in 39 and by segmental resection in 6 patients. Twenty larger granulomas required lobectomy.

Justification for thoracotomy as a diagnostic as well as a therapeutic measure is attested by the fact that there were only two hospital deaths in the entire series, a mortality rate of 1.3%. One of the deaths followed lobectomy for bronchogenic carcinoma in an elderly man who developed postoperative atelectasis and who ultimately died of uremia. The other death also occurred in an elderly man after lobectomy for a mesothelioma. His postoperative course was complicated by the development of a bronchopleural fistula.

The morbidity after operation was slight. Complications requiring treatment occurred in nine patients and included: atelectasis in two, empyema in two, pleural effusion in one, postoperative hemorrhage in one, auricular fibrillation in one, pulmonary embolus in one, and indeterminate fever in one. No attempt has been made to determine the long-time results of the operative treatment.

RECAPITULATION

By use of the clinical means available during the study of these patients, approximately one-third of them were accepted for surgical treatment after the establishment of a preoperative diagnosis. Conversely, two-thirds of the circumscribed lesions in this study were of indeterminate nature. Three important means of establishing a diagnosis were found. Cytological examination of the sputum was extremely useful in the detection of bronchogenic carcinoma. History of previous malignant disease provided a reliable although not infallible clue to the diagnosis of metastatic lesions. The demonstration of calcium in roentgenograms of the chest indicated the benign nature of the lesion, although, in approximately one-fourth of these cases, the distinction could not be made between a hamartoma and a granuloma.

With regard to only the 101 lesions in which the nature was indeterminate prior to exploratory thoracotomy, it was noted that the incidence of bronchogenic carcinoma in this group was similar to that of bronchogenic carcinoma in the entire group of 156 cases, 17%. The same close similarity of incidence applied to bronchial adenoma, hamartoma, and granuloma.

---

[1] Good, C. A.; Hood, R. T., Jr., and McDonald, J. R.: Significance of a Solitary Mass in the Lung, Am. J. Roentgenol., to be published.

Close examination of roentgenograms of the chest not only will disclose the presence of a circumscribed lesion of the lung but also will usually indicate the presence or absence of calcium. Circumscribed lesions may immediately be classified as those containing calcium and those not containing calcium. Since the calcified lesions constitute no important diagnostic problem, they may be set apart. Consequently, the incidence of malignancy in the remaining or noncalcified group is proportionately higher, and the advisability of exploratory thoracotomy is accordingly increased.

COMMENT

Ideally, we should know the exact incidence of the various lesions responsible for the roentgenologic appearance of a circumscribed mass in the lung. Obviously, these figures are not available and we do not mean to imply that the figures reported in this study apply to the total group of patients in whom a circumscribed lesion is discovered. Certain factors of selectivity must inevitably exert an influence on the choice of any group of patients treated by operation. In this instance, in addition to the factors of the patient's refusal of operation and the physician's reluctance to advise an elective operation because of the general poor health of the patient, statistically, the most important selective factor is the physician's own decision that a particular lesion may not warrant surgical exploration. This decision is based, for the most part, on the size of the lesion, the age of the patient, and the lack of symptoms. The bearing of these three factors on the etiological aspects of the lesions in this study has been analyzed. When due consideration is given these factors, it seems that the incidence of various lesions in this study of surgically treated patients approximates their incidence among all patients with circumscribed pulmonary masses.

An attempt has been made to evaluate impartially the various diagnostic procedures available for the study of patients with circumscribed lesions of the lung. Only one laboratory test was of absolute diagnostic value, the cytological examination of sputum. In spite of the fact that these lesions were, for the most part, peripheral in location and, thus, unfavorably situated for the exfoliation of malignant cells, the diagnosis was established by cytological examination of the sputum in 53% of the patients with bronchogenic carcinoma whose sputum was examined.

Two other laboratory examinations were helpful in the evaluation of the lesion under study. The first was determination of the sedimentation rate, which was frequently found to be elevated in patients with malignant lesions but usually not in those with benign lesions. The second was the tuberculin test. A negative reaction in a patient with a circumscribed lesion increases the suspicion of a neoplastic process. It should be borne in mind, however, that patients with neoplastic lesions are just as likely to demonstrate a positive reaction to tuberculin as are others of the same age group. Furthermore, patients with solitary granulomas of the lung may display negative reactions. There appears to be little, if any, need to examine bacteriologically the sputum of these patients. No information regarding the nature of the lesion is to be expected from examination of the blood.

The important role of roentgenologic examination encompasses both the detection and the diagnosis of circumscribed masses. It is the sole means of detection, although its value in diagnosis is limited strictly to the demonstration of calcification. Calcification is the only finding that reliably indicates benignancy. Frequently demonstration of calcification requires the special technique of body-section roentgenography. That more definitive interpretation of roentgenograms is unreliable must be recognized by the attending physician.

Although bronchoscopic examination is considered in some circles as the epitome of a complete preoperative diagnostic study of any patient with a pulmonary lesion, among patients with circumscribed lesions, its use is seldom justified. Only among those whose lesions lie in the region of the pulmonary hilus may any diagnostic findings be expected.

A general appreciation of the value of these various means for the clinical study of patients with circumscribed lesions of the lung should simplify the preoperative program of diagnostic study. We believe that patients whose lesions do not contain demonstrable calcification should have an adequate examination of the sputum for malignant cells, a determination of the blood sedimentation rate, and a tuberculin test. Prolonging the diagnostic study beyond these is, in most cases, without justification, and the decision regarding operation should not be delayed on this account.

In general, it is our policy to consider that the finding of a solitary mass in the lung constitutes an indication for exploratory thoracotomy, unless the benign nature of the lesion appears certain. The latter assurance is totally dependent on the demonstration of calcification. Among the noncalcified lesions in our study, 42% were malignant. Opposed to this, the mortality rate for pulmonary resection in the 156 cases was 1.3%. This indicates that the hazard of observing rather than excising an indeterminate mass is extreme.

It is recognized that the application of these indications for excision is occasionally impracticable because of a patient's poor health. Under such circumstances, careful consideration of factors, such as the patient's age and sex, the nature of the pulmonary symptoms, the size of the lesion, and the appearance of previous roentgenograms, will guide the attending physician and the consulting surgeon to the wisest decision regarding operation.

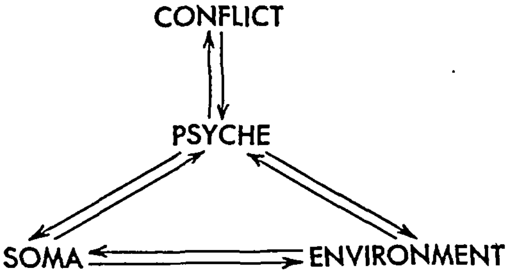
SUMMARY AND CONCLUSIONS

A report is made of a review of 156 cases of solitary circumscribed lesions of the lung in which the mass was completely excised surgically. Approximately 35% of the lesions were malignant, and 65% were benign. No lesion that displayed roentgenographically demonstrable calcification was malignant. The incidence of malignancy among the remaining lesions was 42%. It is concluded that, with few exceptions, the finding of a noncalcified solitary pulmonary mass constitutes an indication for exploratory thoracotomy.

TREATMENT OF "FUNCTIONAL" DISORDERS

Malcolm S. M. Watts, M.D.
and
Dwight L. Wilbur, M.D., San Francisco

There are more hopeful avenues of approach to the management of "functional" disorders than is the case with most "organic" diseases. Indeed, an optimistic attitude toward the management of patients with these conditions is desirable and justified. In this communication a practical method of treatment is described for this group of patients, who constitute so important a part of the practice of many physicians. Emphasis is placed on (1) the therapeutic implications of the actual diagnostic procedures previously described,[1] (2) a successful explanation to the patient of the "functional" nature of his symptoms, and (3) the "definitive" or "specific" management of the precipitating conflict situation, the patient's attitude toward it, somatic symptoms, and the environmental situation. A physician may be able to diminish distressing symptoms immediately, if only temporarily, by use of drugs or other therapy for somatic effect; or he may modify the patient's environmental situation in such a way as to reduce anxiety and tension; or, recognizing the underlying emotional difficulty, he may help the patient by psychotherapeutic means to make a better adjustment.



Extrinsic sources of stress.

The term functional is used to identify the disorders of patients with symptoms of nervousness, fatigue, weakness, insomnia, dizziness, and a variety of other somatic complaints for which no organic cause can be found, because it is felt that the symptoms arise from a disturbance of the function of the patient as a whole. Functional disorders are caused by psychic conflict, and the symptoms are a manifestation of its accompanying anxiety. Sometimes the precipitating cause of the psychic conflict may arise within the psyche itself, and the conflict then is termed intrinsic or "intrapsychic." More commonly, the precipitating factor is extrinsic or "extrapsychic" and arises in the interrelationship between (1) the psyche and the soma, (2) the psyche and the environment, or (3) the soma and the environment (see the chart). Examples of these extrapsychic precipitating factors might include (1) the appearance of hirsutism in a young girl, (2) dissatisfaction of a person with his job, or (3) inability of a person who has had a coronary occlusion to do the hard physical labor by which he earns his living and supports his family.

THERAPEUTIC IMPORTANCE OF DIAGNOSTIC TECHNIQUES

Functional disorders tend to give rise to a common set of symptoms, which may obscure the fact that the stress producing situation is almost always different and highly individualized for each patient or for the same patient at different times. A properly taken and evaluated medical history will permit detection of functional as well as organic disease and also will elicit more or less specific data concerning the precipitating, stress producing situation. The diagnostic features of the history have been discussed previously. Therapeutically, careful diagnosis is important not only as an essential guide in planning the individualized program so necessary for successful treatment but also because in itself it may have a beneficial effect on the patient. If the patient tells his "real troubles," he often shares the load with the physician and is relieved of some of the burden. In addition, the process of taking a good history develops understanding and confidence between physician and patient, which is an essential foundation for therapeutic success.

A thorough physical examination is necessary to confirm the presence or absence of organic disease and, if it is present, to estimate its role in the production of symptoms or disability. Moreover, during the examination, diagnostically important hints of emotional strain or tension may be noted. Examination of the heart or genitals, for example, may evoke an anxious facial expression, flushing, sweating, tremor, or increased pulse rate, indicating undue concern with the part examined. Psychotherapeutically, the physical examination assures the patient that his problem is being treated seriously. It may entirely suffice to convince him that his fears of cancer or heart disease are groundless. When this occurs, anxiety with its symptoms disappears, and the patient is cured. On the other hand, too careful and prolonged or repeated examinations may create or accentuate anxiety if one organ or one part appears to receive undue attention. The physical examination of patients with functional disorders should be thorough, complete, and, if possible, final.

Laboratory studies, roentgenograms, and sometimes consultations may be necessary. They should be adequate to satisfy the physician's conscience. Therapeutically, they are essential to convince the patient that nothing has been overlooked and that he does not have the disease he fears and to provide an adequate basis for explanation to the patient of his difficulty.

[1] Watts, M. S. M., and Wilbur, D. L.: Clinical Management of "Functional" Disorders: The Diagnostic Interview, J. A. M. A. 148: 704-708 (March 1) 1952.

PLANNING FOR TREATMENT

After the diagnostic interview, the physician must decide whether the problem is one he can handle with the knowledge and experience at his command or whether the patient requires more skillful psychiatric care. For the most part, general physicians can adequately treat a patient with conflicts precipitated predominantly by extrapsychic factors, and usually they can help a patient whose problem is predominantly one of intrapsychic precipitating factors of long duration, with occasional exacerbations from extrapsychic factors, that is, the usual psychoneurotic person. Such patients do not respond quickly or well to psychotherapy. Patients with psychotic symptoms, with a notable absence of emotional concern about their condition, or with hysteria or those whose conflicts involve deep guilt or serious disturbance of one of the basic emotional drives should be cared for by a competent psychiatrist. Occasionally, however, a physician may carry some such patients along superficially until they are willing to cooperate in seeing a psychiatrist.

A physician who is treating a patient with a functional disorder must develop a plan tailored to fit the individual problem. This should include a well thought out way to explain the symptoms to the patient and a carefully considered program of specific therapy directed toward the conflict situation, the psyche, the soma, and the environment. The plan will be based on information obtained in the diagnostic interview, the physical examination, and the results of laboratory studies. The physician is guided in what he says and how he says it by his estimation of the patient's intelligence, education, character, past experience, and degree of sexual, psychological, and philosophical maturity as well as by the characteristics of the conflict situation. Successful therapy depends not on the treatment of the symptom complex but on management of the person who has the symptoms. There are many useful therapeutic techniques available. Skillful selection and application of them is the key to success. It is often surprising what can be accomplished.

During the diagnostic phase, symptomatic treatment and specific therapy should be used cautiously. Pain or other disability resulting from organic disease should be relieved, but if symptoms resulting from functional disorders are prematurely relieved, the patient may be satisfied with his temporary improvement and reluctant to carry out the program necessary for ultimate recovery. Anxious patients may ask for tentative opinions or partial reports as studies are progressing. A premature discussion may place the physician in the awkward position of later having to retract or change his statement, thus undermining the patient's confidence. Such a patient may be put off with a statement that his is a complicated problem and that it is best to complete the studies before coming to any conclusions. This is usually appreciated and increases the patient's belief that his problem is being seriously considered and will be satisfactorily solved.

Finally, during this phase, it may be possible to lay some groundwork for therapy; for example, if asked, "Do you think my troubles are all imaginary, Doctor?" the physician may answer that he is sure they are not imaginary but that it is known that such symptoms often result from tension or stress of emotional strain as well as from organic disease. He may add that, while this may be the case, he is not yet in a position to say so until the diagnostic studies are completed. Nevertheless, the seed is planted.

EXPLANATION TO THE PATIENT

Rare nowadays is the patient who is satisfied by the statement, "There is nothing the matter with you; it is all your nerves." The modern patient is indoctrinated through newspapers, magazines, radios, and books in matters pertaining to medicine. His knowledge of medicine is often greater than his physician suspects. These facts contribute largely to the necessity of adequately explaining to the patient the cause and nature of his particular symptoms. Especially in functional disorders, the patient must be convinced of the diagnosis if treatment is to be successful.

In the explanation of the diagnosis, organic disease is considered first. If it is present, the extent to which it contributes to the symptoms and disability is carefully explained. If absent, the evidence for its absence is reviewed. Particular emphasis is placed on diseases the patient thinks or fears he may have. The physical examination and laboratory findings are reviewed. Many patients welcome a chance to see their own x-ray films. If functional disorders are present there will be symptoms not accounted for by any existing organic disease. Evidence that they are functional in nature will usually have been uncovered during the diagnostic interview. The physician certainly must let it be known that he does not look on the symptoms as imaginary, for to tell a patient with headache, for example, that he has no headache is to defeat therapy at the outset. At the same time, the patient must be convinced that the symptoms are the body's "normal" response to prolonged anxiety or tension and are not indicative of a severe or incurable lesion.

It should be relatively easy to show a patient how tension may result in symptoms. One who is called on to make a speech, for example, may feel tense, have a tight feeling in the stomach, and be unable to eat much. Soldiers before a battle may vomit, note urgency of micturition, or have loose stools. Athletes often are tense before an important game. Many persons have experienced tension symptoms while awaiting a reprimand or punishment, perhaps in school. Almost everyone has observed a cat being attacked by a dog and has noted the bodily changes in the cat that result from tension and anxiety. By one or another explanation, the patient is led to accept the fact that anxiety or tension may indeed produce actual functional changes within the body. Then it is emphasized that it is nature's plan for a conflict situation to be resolved by fight or flight and that if the situation persists more or less indefinitely, the organism is subjected to continued stress, which leads to tension symptoms and eventually to fatigue and exhaustion.

Next, the patient is told that a certain amount of tension and stress is a normal part of everyday life. Everyone has anxieties and problems. It is pointed out that each person has a limit of tolerance for tension or stress and that, when this limit is exceeded, symptoms occur. It may be mentioned that symptoms develop in soldiers and airmen who are perfectly normal physically and mentally if they are kept in combat too long or fly too many dangerous missions and that, as soon as they are removed from the stress-producing situation and their total stress load is reduced, the symptoms quickly subside. It is emphasized that there is nothing abnormal or weak about finding oneself in a position in which one's stress load exceeds the tolerance for stress. It happens to almost everyone at one time or another. Every effort should be made to preserve the self-respect of the patient and the feeling that he is respected in the eyes of members of his family and close friends.

It is always necessary that the patient be convinced of the explanation for his symptoms. When the organic and functional components of his difficulty have been explained, the patient should be given an opportunity to ask questions. The physician must have an answer for every question, and the answers must be consistent. When all of the questions have been answered and the patient can think of nothing further to say, the physician is in an ideal position to undertake logical and specific treatment. Sometimes the moment may be indicated by the patient's saying something such as, "Well, how can I get rid of these symptoms?"

AIM OF THERAPY

Specific therapy of functional disorders is directed toward reducing the stress load of the patient and improving his ability to cope with tension. As this is accomplished, the symptoms diminish. When the total stress load no longer exceeds the tolerance of the patient, the functional symptoms vanish. Information obtained during the diagnostic interview[1] and subsequent examination serves as a guide in planning and executing specific treatment to meet the needs and fit the capabilities of the patient. Much depends on the nature and depth of the conflict at the root of the functional disturbance, whether it is intrinsic or extrinsic and whether it is recent and superficial, as in dissatisfaction with one's job, or deep and long-standing and involving the basic emotional drives, as in latent homosexuality.

THERAPY FOR CONFLICT SITUATIONS

For general physicians, it is advisable to attempt no more than superficial treatment of a patient if the factors in the conflict causing functional disturbance are predominantly intrapsychic. Such conflicts are usually deep, are an integral part of the patient's total adjustment, and are best not disturbed except in competent, thorough psychotherapy. In such a case, the symptoms of tension or fatigue and exhaustion usually predominate. If nervousness and tension are the principal symptoms, the patient will usually admit that he has been a nervous, restless person all his life. The physician then may tell him that this is because he has a lot of nervous energy, which is "built in" and is part of him. It may be well to remind him that those who accomplish most in this world are persons with a lot of drive and energy. Usually this explanation suffices, but if the patient is curious as to why he has this troublesome nervous energy it may be wise to mention that it results from difficulties in psychic adjustment in infancy and childhood. Since many such persons are aware, consciously or subconsciously, of difficulties in their early life, they tend to accept this superficial explanation. It is to be emphasized to the patient that this is a normal situation and does not indicate mental disease or insanity. Treatment involves utilization of this nervous and physical energy by suitably increasing physical activities and intellectual interests. This may be difficult to accomplish for a patient who has had, for example, an attack of coronary thrombosis and is suddenly deprived of the accustomed outlets for excess energy. Obviously, other outlets within his physical capabilities must be developed.

When fatigue and exhaustion are long-standing symptoms, it may be explained that there is a lot of "inward tension," which results in a constant state of strain, which in turn causes real physical fatigue and nervous exhaustion. Again, little is said of the causative deep intrinsic conflict situation. Such patients often readily admit they have always been inwardly tense or nervous. Again, if necessary, this may be vaguely explained to be the natural result of difficulties in psychic adjustment in early life. Often in patients of this kind, a vicious circle has been established: symptoms resulting from tension and anxiety are ascribed by the patient to some undiagnosed organic disorder, which adds fear to the stress load and increases the symptoms. The therapeutic problem is to interrupt the vicious circle by removing the fear of organic disease and reducing the stress load. The patient's resistance is also increased by gradually increasing his physical and mental activities and by general supportive measures.

Patients with predominantly intrinsic conflicts often meet complicating extrapsychic, stress producing situations. These add to the total stress load and frequently precipitate the functional symptoms for which the patient consults a physician. Usually, the extrapsychic factor can be identified and overcome and the patient restored to his original, relatively symptom-free state. In these instances, emphasis is placed on management of the extrinsic rather than the intrinsic stress producing factors.

Excellent results are often obtained by exposing extrapsychic precipitating factors. If possible, the responsibility for correlating the symptoms and the conflict situation should be shifted to the patient, for if he himself recognizes the relationship he is more likely to give credence to it than he would be if it were proposed to him by a physician. Getting the patient to have a proprietary interest in the diagnosis may be accomplished in several ways. The physician may say, "You really told me the trouble when you said . . .," or "Your trouble seems to have started when you moved in with your husband's family. Wouldn't you really rather have your own home?" Sometimes it is possible to approach the conflict in such a way that the patient spontaneously takes the final step in recognizing the cause of his difficulty. Once the precipitating factor is in the open and the fact that it causes the symptoms is established, it is a simple matter to point out that the symptoms will persist unless the patient can fight or flee. Often this involves the patient in the making of a decision that has been postponed or avoided. The decision to fight or flee or, equally important, the decision to do neither but to recognize the burden and carry it must be made by the patient himself. The physician may point up the issue and perhaps help to clarify the positive and negative aspects, but the patient must decide. The physician at best can only support the patient's decision. If the conflict situation cannot be avoided or successfully overcome, insight often helps the patient immensely. At least he is relieved of the fear of organic disease, and the physician has other avenues of treatment, discussed below.

IMPROVING THE PATIENT'S ATTITUDE

A second approach to therapy is through improving the patient's attitude. Whitehorn[2] aptly expressed the objective of this when he said, "Psychotherapy will consist largely in the thoughtful and respectful consideration with the patient of how the situation might be met more effectively, not by an ideal person, but by the person who is the patient, using to the best advantage, the assets and attitudes which he has shown in periods of good adjustment. The whole art of psychotherapy depends largely on learning how to exert this special personal influence strategically to meet the patient's best advantage in finding a better way to meet a life-situation." When a general physician attempts to improve his patient's tolerance for stress, his efforts are those of a teacher educating his patient not those of a psychiatrist employing major psychotherapeutic techniques. A sympathetic and uncritical attitude on the part of the physician is a form of supportive treatment. The care taken in diagnosis should assure the patient his symptoms are taken seriously. If the physician seems optimistic and feels that something can be done, this hopeful attitude is transferred to the patient. If the conflict situation cannot be resolved or avoided, the patient is urged to accept his difficulty with equanimity; for example, the physician may call attention to the futility of beating one's head against a stone wall, or he may cite Trudeau's advice that the conquest of fate is achieved not by fighting it or by running away from it but by acquiescence. The physician may help to clarify to the patient his psychic and physiological assets and liabilities. Successful adjustment depends, of course, on taking advantage of one's strong points and minimizing one's weaknesses.

Recently Whitehorn[3] discussed "levels of maturity." At the infantile level, the outstanding need is for affection or attention. The child seeks praise and often alibis to avoid blame. The early adolescent looks for emotional satisfaction in conquest. The mature adult attains a more balanced perspective regarding himself and his work in relation to others. Not all adults are mature, however, and the level of maturity must be considered. If the patient is to be relieved, his emotional needs at his level of maturity must be recognized and provided for, and, sometimes, over the years, a physician may even help a patient develop greater maturity.

More superficially, especially if the conflict situation is to be entirely ignored, the patient may be heartened by reassurance. This is built on a foundation of confidence in the physician and his examination. Its essential components include hope, security, and a feeling of self-esteem. If one of these is lacking, the patient will be disturbed. Hope is supplied by the physician's attitude and perhaps by the good news that there is no serious organic disease; security comes from realization that the problem is being dealt with thoroughly and with understanding and perhaps from a word or two about a good constitution that has stood up well; and self-esteem may be bolstered by a kindly "pat on the back" by the physician, who assures the patient he has handled himself well and has done the right thing all along.

SOMATIC THERAPY

There are three aspects of somatic therapy as used in the management of patients with functional disorders: 1. It is necessary for use in any organic disease that is present. 2. It has definite psychotherapeutic effects. 3. It may be of great help in temporary relief of functional symptoms. If organic disease and a significant functional disorder coexist, the physician should clearly differentiate the symptoms of each in his explanation to the patient. Each should be treated separately.

Frank[4] directed attention to some of the psychotherapeutic aspects of systemic treatment. These should be borne in mind in the management of a patient with functional disorders. One of the pitfalls is that the patient may be made so comfortable he loses his incentive for changing his attitude or solving his conflict. Both the physician and patient may focus attention on symptoms rather than on their cause. The patient may lose confidence if he feels that the physician has failed to seek the true cause of his difficulty. The benefits of symptomatic treatment from the psychological point of view include direct attack on symptoms that may actually be the cause of anxiety, alleviation of symptoms that in themselves may bar approach to the underlying disturbance, and promotion of a favorable attitude by the patient toward the physician, which may create an atmosphere in which the physician can more effectively aid relaxation of the tensions causing the symptoms.

Many of the symptoms of anxiety and nervous exhaustion respond well to sedatives and antispasmodics. The use of sedatives, including various barbiturates as well as chloral hydrate and bromide, is clearly indicated in many cases. Even a fatigued and exhausted patient may feel less fatigued and better able to use his energies productively if he is given sedation. Similarly, sleepless patients given sedatives at bedtime for a week or two may be remarkably improved and regain the poise necessary to cope with a conflict. Occasionally, sympathomimetic drugs (dextro-amphetamine, amphetamine, and methamphetamine), which stimulate the higher nerve centers, may be useful in fatigued patients, but, in general, sedatives are more effective. For patients who are depressed, these drugs may be helpful when used temporarily in adequate dosage. The use of analgesics may be necessary to relieve headache and other aches and pains of functional disorders. These drugs are usually more effective when combined with a sedative. For some patients who are tense and have aching, drugs, such as mephenesin, that relax muscles are helpful. Alcohol, both a sedative and analgesic, may be of great assistance in bringing about relaxation in a tense person at the end of a difficult day, but overindulgence must be avoided. Antispasmodics are useful adjuncts, especially in patients with gastrointestinal tract symptoms of a functional nature.

[4] Frank, J. D.: Psychotherapeutic Aspects of Symptomatic Treatment, Am. J. Psychiat. 103: 21-25 (July) 1946.

Hormones, male and female, have been widely used in treatment of patients with fatigue and anxiety and tension states. While hormone therapy in cases of this type is of questionable value and the results usually disappointing, women at the menopause may benefit considerably from substitution therapy with estrogenic substances. Patients still regard tonics as substances of great value in states of ill health. The benefits of the well-known, old-fashioned ones are largely psychological; however, modern tonics, such as vitamins accompanied at times by iron, have the great advantages of being harmless, of aiding the malnourished, and of having a good psychological effect in that the very term vitamin implies life or vitality. These substances have been widely and shrewdly advertised commercially to conjure an image of brimming salubrity.

For patients with functional disorders, the psychotherapeutic effect of any form of therapy may be great. This applies in particular to therapy with drugs or placebos. Wolf [5] among others, demonstrated the striking pharmacological effect of placebos. Improvement that follows administration to patients of a particular drug or group of drugs may be wholly psychic although the good effect may be attributed by both patient and physician to the pharmacological effect. If the physician maintains a critical attitude in attributing results to drugs that he gives and if medicinal therapy is used intermittently and with adequate psychotherapy and hopefulness, much good can be accomplished and little harm results from use of this form of therapy in patients with functional disorders.

Attention must be given also to general measures in the treatment of functional disorders. The diet should be adequate. Many nervous and tense persons eat poorly and irregularly. A person who drinks 8 or 10 cups of coffee a day because he is nervous may be nervous because he drinks too much coffee. Excessive smoking may also be a cause as well as a result of nervousness. Physical therapy at times is helpful to tide a tense patient over an acute episode. It is expensive and time consuming in the long run. Exercise is always useful in building general body tone. These and many another stimulating measures may be helpful in interrupting the vicious circle of fatigue-anxiety-fatigue in exhausted patients. A patient's activity and rest may be modified as a therapeutic measure. Especially for persons whose underlying conflicts are precipitated primarily by extrapsychic factors, rest is indicated and helpful. Others improve with the avoidance of the conflict situation and with physical and mental rest. Often they improve if they spend a few days in the hospital. On the other hand, patients with predominantly intrapsychic precipitating factors are usually made worse by rest and improve with exercise and increase of their physical and mental activity. This is easy to accomplish in patients who have a lot of nervous energy; difficult in those who are fatigued and exhausted.

An especially difficult patient to manage is one who has a lot of drive and nervous energy and who has been active all his life, yet now has a physical disability, such as myocardial infarction, that limits the activities so necessary for his psychological adjustment. In such circumstances, success depends on inventive development of interests and activities that will absorb the patient's nervous energy without compromising his physical capabilities.

SOCIAL SITUATION

Many patients with symptoms of functional disorders have primarily extrapsychic precipitating factors related to the social or environmental situation. If the precipitating factors can be identified often they can be removed. Even persons with long-standing and deep stress of intrapsychic origin may be thoroughly well adjusted until an extrapsychic or environmental stress or conflict situation is added. They, too, often return to adequate adjustment if the added factor can be removed. A person with ebullience and nothing to absorb it but a boring, sedentary job may improve greatly with a change of occupation. Active hobbies may be developed and social contact encouraged.

If the physician is aware of an extrapsychic source of stress, he may have to weigh the pros and cons of trying to modify it. A man who has worked for 25 years, rising in his organization, may resent the fact that others are now being chosen for the more advanced positions. Financially, he may not be able to afford to give up his job and start again. The physician may find it necessary to balance the disability resulting from this stressful situation against the financial loss that would be entailed in changing jobs. Similar problems arise when the stressful situation concerns marital partners, in-laws, or parents. In such circumstances, a change of climate or a prolonged vacation may be recommended. By these means, the patient's resistance to the stressful situation may be sufficiently increased to permit better adjustment when he again faces it.

Another problem difficult to deal with is anxiety and stress resulting from loneliness, rejection, and insecurity in older age, often the basis of functional disorders in elderly persons. Many American family units are so constituted physically and psychically that there is little provision for the care of an elderly persons. Tensions are inevitable when persons of three generations live under one roof and if members of the older generation are excluded and rejected. Sometimes the family may be reminded of its responsibility to provide to some extent for the needs of grandmother. Usually, the major effort is toward improvement of her stress tolerance. A word to a member of the family or an understanding mutual friend may suffice to materially reduce an extrapsychic source of stress. At times, an understanding pastor is most helpful.

Occasionally, a vicious circle is established between tension symptoms and an environmental stress; for example, tension symptoms may develop in a person with a pending compensation claim, which progress as negotiations are prolonged and thus prolong the negotiations. The vicious circle is relieved only by a settlement that resolves the conflict. If settlement is long delayed, severe functional symptoms may develop, which may be considered related to the precipitating accident or injury but which are actually due to failure to reach a settlement. Such a situation may be expensive to the compensating agency.

PREVENTION OF RECURRENCES

Successful management of patients with anxiety and nervous exhaustion does not end with control of the presenting situation. Many patients will have recurring bouts of tension and anxiety, and of this they should be forewarned. Such a patient should be taught better methods of adjustment to lessen tension and should be told to expect symptoms whenever his tolerance for tension is exceeded. He may learn to avoid situations that will result in anxiety and tension. Through treatment, he may develop insight into his symptoms and build up his stress tolerance to the maximum. He may be taught to avoid long and needless worry about new or persistent symptoms and may be urged to bring problems to the physician and trust him to evaluate the importance of them. The patient should be encouraged and helped to plan for a future that will keep him as content as possible and free of symptoms. His life expectancy is often far greater than he believes.

SOME CAUSES OF FAILURE

Most patients who consult a physician about symptoms of functional disorders will respond to a greater or lesser extent to a program based on the diagnostic and therapeutic principles that have been outlined. If the patient does not improve at all, it is important that the physician know why. Incorrect diagnosis frequently results in a dissatisfied and disturbed patient and physician. If the physician's explanation of a situation does not convince the patient, it will not support the therapeutic program. Failure to fit the treatment aptly and specifically to the peculiar problem of each patient may be the cause of poor results. The general physician is often the first to see a patient with true psychosis or with borderline psychotic manifestations. Such conditions, usually easy to recognize if suspicion of them is kept in mind, of course, call for care of the patient by a competent psychiatrist.

Organic disease should always be considered in cases in which functional symptoms do not fit any of the usual patterns or in which there is no detectable cause for symptoms and yet the patient does not respond satisfactorily to management. It is well known that patients with brain tumor sometimes have been treated for considerable periods as having functional disturbances. Of course, functional disease and organic brain disease may coexist.

RESISTANCE SYMPTOMS

Hart [6] in a recent paper called attention to resistance symptoms. These were described as having become a necessary and integral part of the patient's psychic adjustment. If resistance symptoms are relieved, the patient's adjustment is destroyed, and anxiety and tension become acute. Therefore, although sick and miserable, subconsciously he knows he must avoid being cured. Hart pointed out many of the characteristics of such persons. They procrastinate in seeking medical attention and they indulge in self-treatment, medical shopping, patronage of cults, broken appointments, and sabotage of treatment. They often appear complacent and deny difficulties. They fear and avoid any attempt at personality study. Interestingly, they are often happy and eager to try, once more, remedies they have previously found ineffective. They are difficult, indeed, to cure.

SUMMARY

In treatment of patients with symptoms stemming from functional disturbances caused by anxiety and tension, the diagnostic technique in itself is to some extent therapeutic. It supplies the physician with information he must have for tailoring a program of therapy to fit the peculiarities of the patient and his problem, and it can also be carried out in such a way as to convince the patient he is being dealt with competently and sympathetically, a long step toward relief and receptiveness to further therapy. It is essential that the patient believe the diagnosis to be correct. Simple illustration of the somatic response to psychic stimulus usually helps toward that end. The physician should determine in the course of the diagnostic procedure whether the cause of the disturbance is principally extrapsychic or intrapsychic, that is, whether tension is owing in the main to the effect of worry over a somatic disease or an environmental situation by a patient otherwise well adjusted or only in small part to the effect of such factors on a psyche in which conflict is deeply rooted and of long standing. The precipitating factor causing the tension should be identified, and specific treatment should be directed toward curing any somatic disease that may be present, allaying fear of disease that is not present, and improving the environmental situation or helping the patient to make better adjustment to inescapable burdens. Ego building, reassurance, and approbation often have beneficial effects. Analgesic or sedative drugs may be helpful in some circumstances, but the patient should not be permitted to depend on them indefinitely. In dealing with patients with deep-lying psychic conflicts of long standing, a general physician should not attempt to do more than deal with factors immediately involved in the production of symptoms, and he should not give more than perfunctory explanation of the deeper conflicts. Often the problem with patients of this kind is to provide benign outlets for excessive drives and energies. In some cases, this may require considerable inventiveness. Failures in therapy may result from incorrect diagnosis or inept tailoring or application of the program of treatment to the peculiarities of the conflict situation or the patient and sometimes from the fact that the patient resists therapy because the symptoms are an integral part of his adjustment.

ARTERENOL IN TREATMENT OF SHOCK

A. J. Miller, M.D., A. Shifrin, M.D., B. M. Kaplan, M.D., H. Gold, M.D., A. Billings, M.D.
and
L. N. Katz, M.D., Chicago

The management of the various types of shock, each characterized by its own combination of circulatory disturbances,[1] is still far from perfect. Recently, the employment of intra-arterial transfusion[2] and vasopressor drugs[3] for shock has begun to receive increasing attention. The present report is a clinical evaluation of arterenol, a vasopressor drug, in the treatment of shock from various causes.

RATIONALE OF VASOPRESSOR DRUG THERAPY IN SHOCK

Whole blood is the most effective substance to combat shock due to hemorrhage; however, blood (or plasma) is not always immediately available, and other methods of treatment must be employed in the interim. Furthermore, blood and blood products, on occasion, are not effective in reversing the profound hypotension of severe blood loss, and adjuvant therapy is then desirable. Under these circumstances, vasopressor drug therapy would be indicated to combat the severe peripheral vascular collapse.

Severe cardiogenic shock, initiated by the inability of the left heart to maintain an adequate output,[4] is not rare after acute myocardial infarction and is associated with a mortality rate of 75% or higher.[5] Good therapeutic results have been reported with intravenous plasma and blood transfusions,[6] but this approach has generally been considered to have relatively little value.[7] Intravenous administration of blood may aggravate existing pulmonary edema. This may be avoided to some extent by the use of intra-arterial transfusions. The latter have been used by Silber and co-workers[2a] and Berman and Akman,[2b] and the reported results have been encouraging enough to merit further clinical evaluation. It has been previously suggested that intra-arterial transfusion combined with vasopressor drugs may be a more effective therapeutic approach to cardiogenic shock than any heretofore utilized.[3a] Increasing attention has been paid to the use of vasopressor therapy in cardiogenic shock, the primary stimulation to the more recent work being the discovery of vasopressor substances with potent peripheral action and without evident aggravation of myocardial irritability.[8] The aim of the use of vasopressor drugs in the treatment of shock following acute myocardial infarction is to increase the mean aortic pressure and thus reestablish an adequate coronary blood flow. Hellerstein and Brofman[9] have pointed out that the ideal pressor drug would increase peripheral resistance, elevate blood pressure, produce a proportionate increase of coronary flow, and have minimal side-effects and would not decrease cardiac output or produce serious arrhythmias.

Shock following toxemia, infection, or drug intoxication or due to neurogenic factors is associated with peripheral vasomotor collapse and the redistribution and pooling of blood. The primary aim of therapy is, therefore, to increase the effective circulating blood volume. Whole blood or plasma transfusion is often satisfactory, but, when severe circulatory collapse is present, the shock may not resolve with this therapy alone. Inasmuch as the primary problem appears to be a loss of vasomotor tone,[1] vasopressor drugs theoretically should have a desirable therapeutic effect.

PHARMACOLOGY OF ARTERENOL

Arterenol (nor-epinephrine) is an amine that has been proved a potent vasopressor drug in man.[10] Its presence has been shown in the adrenal medulla of cattle,[11] and it undoubtedly plays an important role in impulse transmission in postganglionic adrenergic nerves.[12] It has been found in high concentration in pheochromocytomas,[13] and an etiological relationship to essential hypertension has been suggested.[8b]

In the isolated surviving coronary arteries of healthy, slaughtered swine, arterenol is said to produce two and one-half times the vasodilatation produced by *l*-epinephrine.[14] Arterenol causes significant increases in coronary artery blood flow in animals,[15] although a decreased coronary flow has been reported with small doses.[16] It has been suggested that the coronary vasodilatation may be wholly or partly secondary to stimulation of the myocardium.[17]

In man, arterenol causes generalized vasoconstriction of arterial, capillary, and venous blood vessels and a resultant increase in total peripheral resistance.[8b] It tends to slow the pulse rate, an effect abolished by atropine. It produces an increase in cerebrovascular resistance and a decrease in cerebral blood flow, despite the increase produced in mean arterial blood pressure, and no significant change in oxygen consumption.[18] Sensenbach and Ochs[19] found, however, no significant fall in cerebral blood flow. Arterenol produces a decrease in renal plasma flow, leaves the glomerular filtration rate relatively unchanged, and usually produces an increase in urine flow.[20]

Arterenol has been used effectively to prevent hypotensive phases during sympathectomy,[21] and Goldenberg and his associates[3b] have used it successfully in treatment of patients with oligemic shock in whom blood therapy alone was not satisfactory. No serious cardiac arrhythmias were reported during its administration, and surprisingly few subjective sensations were manifest, despite pressor effects of considerable magnitude. Baker

---

The arterenol (Levophed) used in this study was supplied by Winthrop-Stearns, Inc., New York.

From the Cardiovascular Department, Medical Research Institute, and the Department of Medicine, Michael Reese Hospital.

Because of space limitations, table 1 and all of the bibliographic references have been omitted from THE JOURNAL and will appear in the authors' reprints.

This study was aided by the Michael Reese Research Foundation, a grant from Winthrop-Stearns, Inc., New York, and the Herbert G. Mayer Memorial Fund for Cardiovascular Research.

Cases 2 and 3 are reported with the permission of Dr. Lyle A. Baker, Chief, Department of Medicine, Veterans Administration Hospital, Hines, Ill. Dr. Lester Baker made abstracts of the records of these cases.

and one of us (A.J.M.)[3a] observed no undesirable effects on the prevailing cardiac rhythm or the subjective status during the administration of arterenol to patients in shock following acute myocardial infarction. Pressor responses were obtained in six of seven patients studied. Recently, Kurland and Malach[3d] reported significant pressor responses in 12 of 17 courses of treatment in 14 patients in cardiogenic shock. They also confirmed the absence of untoward cardiac rhythms or subjective reactions during the use of arterenol.

METHOD

Thirty-two patients in shock from various causes were treated with arterenol, the arterenol being used in addition to other appropriate measures. All the patients were severely ill. The duration of shock prior to the institution of arterenol therapy varied. The degree of shock present in each case was arbitrarily classified as "moderate," "severe," or "profound," on the basis of an impression of each patient's clinical status. Vasopressor responses were classified as "excellent" when the blood pressure was elevated to within normal limits, "fair" when the blood pressure rose but did not reach the normal range, and "poor" when little or no blood pressure response was obtained.

Table 2.—*Results of Arterenol Therapy Classified According to Probable Major Cause of Shock*

* Systolic arterial blood pressure raised to 100 mm. Hg or higher.
† Systolic arterial blood pressure significantly elevated but lower than 100 mm. Hg.
‡ No elevation in systolic arterial blood pressure.
§ The other patient died 21 days after the episode of shock.
‖ One patient died six days after an emergency subtotal gastric resection; one had carcinoma of the colon with generalized metastases.
¶ One patient died nine days after the episode of shock.
# In four patients the ultimate prognosis was hopeless.

The solutions for infusion were generally prepared by adding 4 cc. of a 1:1,000 solution of arterenol to 1,000 cc. of 5% glucose in water or 0.9% sodium chloride in water. (In one instance arterenol was added to plasma). The resultant solution contained 4 μg of arterenol (as the bitartrate) per cubic centimeter. When it was desired to limit the total amounts of fluid administered, arterenol solutions were prepared in greater concentration (e. g., 16 μg or more per cubic centimeter).

The infusions were begun in one of two ways. Usually, they were started at the rate of 10 to 15 drops per minute and increased by about 5 drops every three minutes, until the desired blood pressure was obtained. Frequently, the rate of administration was initially fairly rapid (e. g., 60 drops per minute) and then was adjusted to hold the blood pressure at the desired level with the minimum rate of administration. The infusions were stopped by decreasing the rates of flow by small amounts and observing the effect on the blood pressure. If the blood pressure tended to fall, arterenol therapy was continued; if the blood pressure maintained itself, the rate of infusion was decreased gradually and finally stopped. Ordinary intravenous infusion sets were used, no attempt being made to calibrate the exact amounts of drug given per unit time.

RESULTS

The results of treatment are summarized in tables 1 and 2. Thirty-two patients were treated for 40 episodes of shock. A satisfactory pressor response was obtained in 33 instances; in 5 instances the blood pressure was raised but not out of shock levels; in the remaining 2 there was no pressor response. In half the patients studied cardiogenic factors were primary or of major importance in the initiation of shock, and in the other half the shock was primarily noncardiac in origin.

Nine patients had shock following acute myocardial infarction. In eight, excellent pressor responses were obtained; two (cases 24 and 27, table 1) were relieved of shock on two separate occasions, and one other (case 32, table 1) had a satisfactory pressor response during each of the five episodes of hypotension. Five of the nine patients survived, two of whom (cases 27 and 24, table 1) were having, respectively, their second and third myocardial infarctions. Three of the five surviving patients and two of the four who eventually died were digitalized before or during arterenol therapy. Only one of the nine patients (case 10, table 1) was in known shock for longer than three hours before arterenol treatment was begun. This patient, who had severe hypertension and chronic congestive heart failure prior to coronary occlusion, died despite the achievement of a good pressor response (not, however, to previous levels) with arterenol. In one patient (case 13, table 1) 500 cc. of whole blood was given intra-arterially during the time arterenol was being infused and had already resulted in a moderate pressor response. This patient died more than 20 hours after arterenol therapy was started, despite elevation of the blood pressure to 100/80.

Three patients treated for shock had acute myocarditis in addition to another basic disease process. All three died, although two had excellent pressor responses. All were digitalized. One patient (case 21, table 1) with bulbar poliomyelitis survived for more than 36 hours after arterenol therapy was instituted. There was no doubt of the efficacy of arterenol in maintaining the blood pressure, although very large dosages were required.

One patient in shock associated with virus pleuropericarditis and pleural effusion (case 23, table 1) recovered after arterenol therapy. A digitalized patient in chronic congestive heart failure went into cardiogenic shock shortly after right heart catheterization (case 15, table 1). An electrocardiogram at this time was compatible with acute coronary insufficiency, and this was confirmed in a subsequent record. Arterenol resulted in remarkable improvement, the blood pressure being elevated from 50/? to 100/70. Thereafter the patient made an uneventful recovery. Two patients (cases 1 and 9, table 1) with pulmonary embolism were successfully treated for shock; the first survived for 21 days, while the other was discharged from the hospital after 20 days. Both patients were digitalized, and one received quinidine for frequent premature ventricular systoles.

Sixteen patients were treated for shock of noncardiac origin. Three (cases 2, 3, and 16, table 1) were treated for shock following massive gastrointestinal blood loss until whole blood could be obtained; in two of these excellent vasopressor results were achieved. Two patients (cases 12 and 30, table 1) treated for shock after rupture of the abdominal and thoracic aortas, respectively, had excellent blood pressure rises. Successful relief from shock was obtained in one patient (case 11, table 1) with a ruptured ectopic pregnancy and in another patient (case 29, table 1) with empyema of the gallbladder. In both instances arterenol treatment permitted surgical intervention, and both patients survived. Vasopressor therapy was successfully used in a patient with barbiturate intoxication (case 4, table 1); this patient survived deep coma and two separate episodes of severe shock.

A dramatic result was achieved in a patient with anaphylactic shock (case 28, table 1), the blood pressure being quickly raised from 40/0 to 110/80. Treatment was necessary for only one-half hour, during which time erythematous wheals on the arms and face showed considerable improvement. One patient (case 19, table 1) who survived a period of shock following myocardial infarction also had serum sickness, a diffuse erythema, and urticaria. While arterenol was being given, the erythema showed considerable improvement, and the urticaria almost disappeared. When arterenol therapy was stopped, the urticaria recurred.

Arterenol was given continuously in this series of patients for ½ to 36 hours, with ill effects becoming manifest. All except one of the patients had rapid heart rates; arterenol slowed the rates in some. In no instance was the rhythm altered. One patient had advanced atrioventricular block, four had multiple premature systoles, and one had auricular fibrillation. Congestive heart failure was neither precipitated nor manifestly aggravated by arterenol. In 14 patients, digitalis or one of its derivatives was used before or during arterenol treatment. All of the patients treated in this series were gravely ill, and permission was often given for arterenol to be used only as an heroic measure. In five patients (cases 7, 12, 14, 16, and 30, table 1) it was known that the ultimate prognosis was hopeless, and arterenol was used only to evaluate its pressor effect. The noteworthy local complications of arterenol therapy were few. One patient who survived an episode of shock subsequently had sloughs of skin from the dorsal surfaces of each hand at the sites of the venipunctures. Another patient had thrombosis of an antecubital vein. Blanching of the skin near the site of venipuncture was observed often.

COMMENT

The results of the present study definitely establish arterenol as a valuable adjuvant in the treatment of shock. It was effective in treatment of shock due to blood loss; nevertheless, oligemic shock should be treated with this drug alone only as a means of interim care until blood and/or plasma is obtained. Its prolonged use alone may mask continued blood loss, and there is no evidence that arterenol, by virtue of its vasoconstrictor action, tends to stop or slow bleeding. In cases in which intravenous administration of whole blood alone is not effective in reversing shock due to blood loss, the use of vasopressor therapy would appear to be mandatory. This study and others cited revealed no undesirable responses from the use of arterenol in treatment of oligemic shock. Further experience may establish that the immediate utilization of arterenol along with whole blood is the most conservative method of treating severe shock, the aim of good therapy being to reverse the state of shock as quickly as possible. Finally, arterenol may prove of increasing value in patients with persistent blood loss who require emergency surgery.

Our results confirm the absence of enhanced myocardial irritability, as evidenced by clinical criteria, when arterenol is administered to patients in severe shock following myocardial infarction. There was also no evidence of increased myocardial irritability when arterenol was used to treat shock in myocarditis and pulmonary embolism. There was no instance of untoward effect on the prevailing cardiac rhythm, and no undesirable subjective reactions were observed. The relief of hypotension was generally associated with objective evidence of clinical improvement. The over-all survival rate of patients in cardiogenic shock was higher than in a study previously reported by Baker and one of us (A.J.M.)[3a]; however, in the previous study the criteria for treatment demanded a systolic blood pressure of 80 mm. Hg or less and a duration of shock of at least four hours. Thus, the prognosis for those patients was extremely grave. The better results obtained in the present study are probably in part a reflection of the earlier treatment of the shock. We believe that severe cardiogenic shock demands therapy and agree with Hellerstein and Brofman[9] that the most efficacious method of treatment now available is use of vasopressor drugs. Inasmuch as arterenol has proved a relatively safe drug when used with proper precautions, there need be no procrastination about the institution of early therapy. It is important to remember, however, that this drug can in no way replace the standard treatment measures for complications of cardiogenic shock or events occurring concomitantly with it. Such problems as congestive heart failure, embolic phenomena, and cardiac arrhythmias should be treated by the known and appropriate measures. Digitalis or its derivatives should be used without hesitation in the treatment of congestive heart failure. Arterenol produced impressive vasopressor responses in patients with shock that was not primarily of oligemic or cardiac origin. Use of vasopressor drugs would seem logical when the primary defect is a loss of vasomotor tone.

Experience with the use of arterenol has shown that there occasionally is a need for large dosages to achieve a satisfactory vasopressor response. No undesirable effects were noted with doses as high as 100 drops per minute of a solution containing 32 μg of arterenol bitartrate per cubic centimeter. Sometimes relatively small amounts of arterenol have produced excellent vasopressor results, and it is for this reason that we suggest starting the infusion slowly and gradually increasing the rate of administration until the desired arterial blood pressure is attained. We believe it advisable to decrease the rate of flow slowly when the infusion is to be discontinued, rather than to stop it abruptly.

The considerable amount of investigative work with arterenol, although sometimes contradictory, generally points to the increasing value of this drug in clinical medicine. Final evaluation will have to await studies of larger numbers of patients with various types of shock. One problem that has arisen, on which the present investigation sheds little light, is the unpredictability of arterial blood pressure responses to particular dosages of arterenol. Fritz and Levine [22] and Ramey, Goldstein, and Levine [23] have shown that dogs whose adrenals have been removed do not show the same response to arterenol as normal control dogs, that arterial blood pressure cannot be maintained by continuous infusion of arterenol as in normal controls, and that the mesoappendix of the rat without adrenals becomes refractory to repeated topical applications of arterenol. The diminution or lack of response in animals whose adrenals have been removed was reversed by administration of adrenal cortex extract.

This work may have clinical application in episodes of shock not responsive to arterenol or in those in which very large doses of the drug are required to obtain a pressor response. In some of these patients, adrenal "exhaustion," with diminished secretion of adrenal cortical hormones, may diminish blood vessel reactivity to arterenol. Two other factors must also be considered, however. It is undoubtedly true that in certain instances of shock, or at certain times in the sequence of events leading to the clinical picture of shock, maximal vasoconstriction is already present owing to intrinsic compensatory mechanisms. Arterenol would not be expected to have a significant vasopressor action under such circumstances if its role is solely that of a vasoconstrictor. The experiences reported here show that arterenol generally does raise the arterial blood pressure in patients in shock. Our data cannot, however, be used to elucidate the mechanism by which this result is obtained. The presumptive evidence, from studies in normal persons, indicates the major factor to be one of increased peripheral resistance secondary to vasoconstriction, but the factor of increased cardiac output remains a possibility when shock is present. Studies in normal persons, though of definite value, cannot be directly transposed to explain why arterenol raises the blood pressure in persons with shock. It definitely can be stated that, if increased cardiac output is a factor, it does not occur by means of an increase in heart rate.

Thus, failure to obtain a satisfactory rise in arterial blood pressure in patients in shock by treatment with arterenol may be dependent on (1) an inability of the blood vessels to respond with sufficient vasoconstriction, (2) the presence of maximal vasoconstriction before arterenol is given, or (3) the inability of the heart to respond with an increased output. More than one of these factors may be operative. In the light of our results, we consider the second possibility to be unlikely in cases of severe or profound shock from any cause. The first possibility, already demonstrated by Levine and his group [24] in animals, will require confirmation in man. The evaluation of the relative roles of alterations in cardiac output and total peripheral resistance in response to arterenol used in treatment of shock will have to await appropriate studies.

SUMMARY

Arterenol, a pressor amine, has been used in the treatment of 40 episodes of shock from various causes in 32 patients. Nine patients were in shock following acute myocardial infarction. Excellent pressor responses were obtained with treatment in 25 of the 32 patients; in five patients the pressor response was moderate, and in two there was no response. The results strongly suggest arterenol to be a valuable adjuvant to the therapy of shock. There was no evidence that arterenol increased myocardial irritability. No undesirable subjective reactions were noted. In no instance was heart failure precipitated or aggravated by arterenol, and there were no apparent ill effects in patients digitalized before or during arterenol therapy. Further evidence for the value of vasopressor therapy in the treatment of cardiogenic shock is given. Arterenol was effective as interim therapy of oligemic shock until whole blood could be obtained. It was of value in the treatment of shock associated with barbiturate intoxication, bulbar poliomyelitis, virus pleuropericarditis, ruptured ectopic pregnancy, and empyema of the gallbladder. Anaphylactic shock was also successfully treated.

29th St. and Ellis Ave. (16) (Dr. Katz).

Health and Obesity.—Obesity is both disadvantageous and dangerous. . . . Obesity predisposes to diabetes, increases the tendency to hypertension, favors the development of atherosclerosis and contributes to heart failure. It increases the incidence of gallstones. It causes shortness of breath on exertion, intolerance to heat and excessive sweating. It leads to maceration, intertrigo, eczema and furunculosis. It fosters the development of postural emphysema, flat feet, hernia and osteoarthritis of the hips and knees. In every physical activity, its presence constitutes a burden varying only with the degree of adiposity. It is unesthetic, socially unacceptable and psychologically crippling. It shortens a life that has been made ridiculous and miserable by its presence.—D. P. Barr, M.D., Health and Obesity, *New England Journal of Medicine,* June 4, 1953.

NEW APPROACH TO THE TREATMENT OF INTRACTABLE VERRUCA PLANTARIS (PLANTAR WART)

Henri L. DuVries, M.D., Chicago

It is not generally appreciated that new growths of the skin on the plantar surface, especially those occurring under the heads of the metatarsals or any weight bearing area of the foot, often become a major disabling problem. A pebble or nail inside a shoe can make standing or walking next to impossible; a deep-seated callus or residual scar can do likewise, if located under a weight bearing area. The disability these growths may cause varies from a constant discomfort to complete inability to bear weight over the area. The patient often states that bearing weight on the area is like "stepping on a tack."

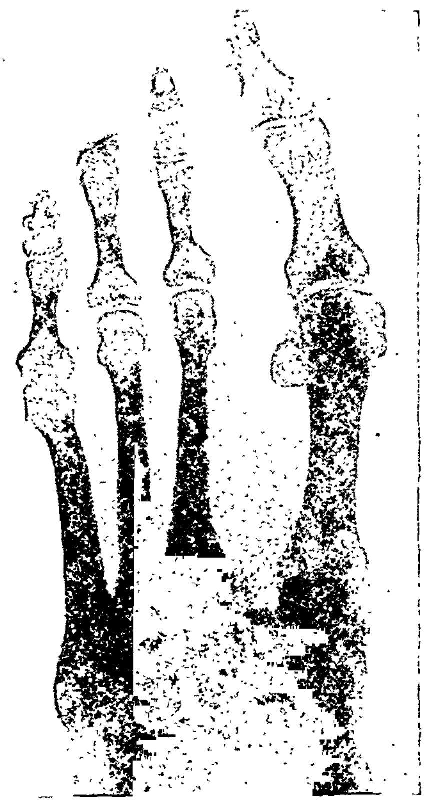

Fig. 1*B*.—Postoperative view of foot with intractable verruca plantaris under the second left metatarsal head after Dickson's procedure.

That some authorities have been aware of the seriousness of these problems is attested to by the drastic operations they have recommended. Dickson [1] suggests excision of the entire metatarsal shaft, together with dorsal and plantar soft structures covering it, including the toe. In regard to this procedure, a 42-year-old woman was first seen by me in February, 1952, with the complaint of an intractable verruca plantaris under the second left metatarsal head. A few days before the appointed date for surgery, Dickson's procedure was performed elsewhere. I saw her again in February, 1953, when she presented a linear scar studded with multiple clavi along the medial side of the entire shaft of the third metatarsal. She is more incapacitated than formerly (fig. 1). Blair [2] advises excision of the growth and its surrounding tissue and pedicle grafting from a non-weight-bearing surface of the sole of the foot.

Formation of this type of new growth occurs most frequently under the middle three metatarsal heads (fig. 2*A*). It is in this area that they oftenest become intractable and are usually referred to as plantar warts. It is open to question whether many of these growths are verrucae. I see many seed-like calluses under the plantar condyle surfaces of the metatarsal heads, containing white connective tissue fibers of a reactive fibrosis, secondary to the prolonged trauma of pivotal weight-bearing on a pointed condyle. Such a callus is often diagnosed as verruca plantaris and treated by irradiation, escharotics, electrodesiccation, or surgical excision of the mass. Many patients have been treated by all of these methods. The mass of scar tissue resulting from each type of treatment has been greater than the original excrescence, with increased disability. A comparable but less disabling condition occurs under the head of the first metatarsal and is usually due to an anomalous or hypertrophied tibial hallux sesamoid. New growths are uncommon under the head of the fifth metatarsal, but minor callosities are common.

The plantar surface of the head of each metatarsal has two condylar projections. Those of the middle three metatarsals end in sharp points extending proximally (fig. 2*B*). The condyle on the fibular side is always the larger. Because depression of the anterior arch is nearly a universal malady of civilized man, these condyles assume full weight bearing function. During walking they bear an added pivotal backward thrust for a short period during each step. This thrust results in the condylar points gouging into the soft understructures. These projections vary in size and shape from one metatarsal to another and in different persons. The plantar condyles of these metatarsals may vary from a mere rudiment to a projection higher than any other weight bearing point under all the metatarsal heads and from a ball-like surface to a pinpoint (fig. 2*B* and 2*C*). The sharper and more projective the condylar points the more the person is subject to fibrotic changes in the skin and subcutaneous tissue of this area. The skin under such a condyle accumulates horny cells as a protective measure, and a vicious cycle is produced: the greater the accumulation of horny layers the less space between the condylar surface and contact area, resulting in further compression of the soft tissues covering these areas and their gradual degeneration.

From the Department of Surgery, Columbus Hospital.

Because of lack of space, some of the figures and reports of cases have been omitted from THE JOURNAL and will appear in the author's reprints.

TREATMENT

In the past four years, I have excised 23 plantar condyles of the metatarsal heads of 21 patients, aged 23 to 62 years, with intractable growths immediately under the head concerned. There was complete relief in the majority of cases and marked improvement in all others. Fourteen (64%) of the patients were women. One woman and one man had growths bilaterally: in the woman the second metatarsal head of both feet were involved, whereas in the man the third metatarsal head of both feet were so afflicted. The second metatarsal head was involved in 12 cases (52%), the third in 8 cases (34%), and the fourth in 3 cases (13%). Three of the patients had had no previous treatment, five had had electrodesiccation and escharotics, four had had electrodesiccation, escharotics, and radiation therapy, three had had just radiation therapy, two just escharotics, two electrodesiccation, escharotics, radiation therapy, and excision, and one each just excision and electrodesiccation only.

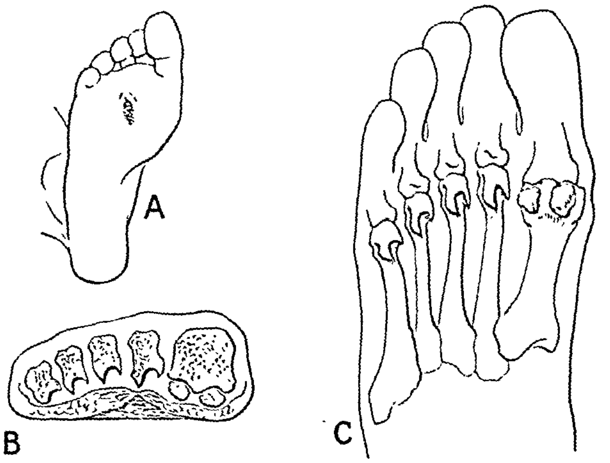

Fig. 2.—Location of verruca plantaris in plantar area. *A*, usual appearance of a new growth or scar under a metatarsal head. *B*, cross section of metatarsal head 0.5 cm. behind articular surface, showing condylar process. *C*, plantar view of metatarsal heads. Note that the fibular condylar process is normally the larger.

An incision is made immediately over the involved metatarsal phalangeal joint. The skin and extensor tendon are retracted, and the capsule is incised longitudinally (fig. 3). The capsule is then retracted with the skin margins, and a vertical incision is made in each side of the joint capsule (fig. 4); this frees the head of the metatarsal so that it can be delivered dorsally. The involved toe is plantar-flexed by the thumb of the surgeon's left hand, while the index finger of the same hand is applying pressure on the plantar surface of the metatarsal. This delivers the head of the metatarsal out of the wound (fig. 5). The plantar condyle is now amputated (fig. 6), and the surface is smoothed and rounded with a Joseph nasal rasp (fig. 7*A*). The capsule is closed with interrupted sutures (fig. 7*B*), and the skin margins are sutured.

REPORT OF CASES

Case 1.—The patient was a 54-year-old white male barber. For 10 years he had had a callus under the head of each third metatarsal. About seven years ago the condition was diagnosed as verruca plantaris, and electrodesiccation was employed, without relief. Two years later the growths were irradiated. Increase in size of the growths and resultant disability compelled the patient to give up barbering in 1950, because of inability to stand. Physical examination and routine laboratory findings were normal. In September, 1950, I removed the plantar condyles immediately over the growths. The patient was able to return to work, practice his trade two months later, and is to this day free from pain.

Case 2.—A 32-year-old white female waitress, in the spring of 1950, noted a growth under the second right metatarsal head, which was painful on weight bearing. The mass was diagnosed as verruca plantaris and excised. It recurred soon after healing of the wound. Some months later it was treated by electrodesiccation; again it recurred, more painful than ever. This was followed by many attempts to destroy the growths by escharotics. She first came under my care Sept. 8, 1952, with the complaint of inability to retain employment because she was unable to bear weight on the ball of her right foot.

On examination I found a cicatrix 2.5 by 1 cm. under the head of the right second metatarsal, whose center contained papillary formation resembling verruca tissue surrounded by scar (fig. 8). The mass was not adherent but penetrated the subcutaneous tissue and fascia. Results of routine physical examination and usual laboratory tests were normal. On Sept. 29, 1952, the plantar condylar surface of the second right metatarsal head was excised. The patient made an uneventful recovery and was able to bear weight comfortably on the ball of her right foot three weeks postoperatively. Since then the mass has almost disappeared (fig. 9), and she is completely free of pain.

SUMMARY

Verruca plantaris (plantar wart) and deep-seated calluses occur commonly under the metatarsal heads and often become a major disabling problem. Prevailing treatment often leaves disabling residual scar, and the radical procedures performed on intractable cases produce deformity. A new surgical approach to alleviate this malady is outlined. Twenty-one cases that have been successfully treated by this procedure are recorded.

NEW APPROACH TO THE TREATMENT OF INTRACTABLE VERRUCA PLANTARIS (PLANTAR WART)

Henri L. DuVries, M.D., Chicago

It is not generally appreciated that new growths of the skin on the plantar surface, especially those occurring under the heads of the metatarsals or any weight bearing area of the foot, often become a major disabling problem. A pebble or nail inside a shoe can make standing or walking next to impossible; a deep-seated callus or residual scar can do likewise, if located under a weight bearing area. The disability these growths may cause varies from a constant discomfort to complete inability to bear weight over the area. The patient often states that bearing weight on the area is like "stepping on a tack."

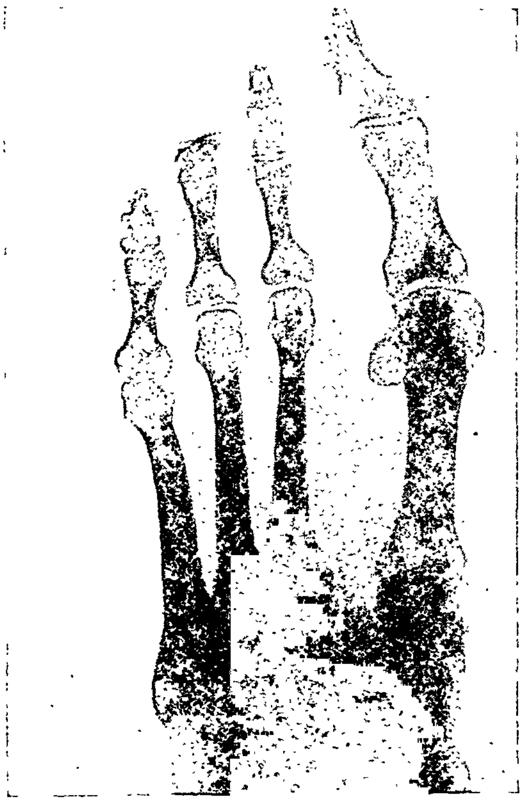

Fig. 1*B*.—Postoperative view of foot with intractable verruca plantaris under the second left metatarsal head after Dickson's procedure.

That some authorities have been aware of the seriousness of these problems is attested to by the drastic operations they have recommended. Dickson [1] suggests excision of the entire metatarsal shaft, together with dorsal and plantar soft structures covering it, including the toe. In regard to this procedure, a 42-year-old woman was first seen by me in February, 1952, with the complaint of an intractable verruca plantaris under the second left metatarsal head. A few days before the appointed date for surgery, Dickson's procedure was performed elsewhere. I saw her again in February, 1953, when she presented a linear scar studded with multiple clavi along the medial side of the entire shaft of the third metatarsal. She is more incapacitated than formerly (fig. 1). Blair [2] advises excision of the growth and its surrounding tissue and pedicle grafting from a non-weight-bearing surface of the sole of the foot.

Formation of this type of new growth occurs most frequently under the middle three metatarsal heads (fig. 2*A*). It is in this area that they oftenest become intractable and are usually referred to as plantar warts. It is open to question whether many of these growths are verrucae. I see many seed-like calluses under the plantar condyle surfaces of the metatarsal heads, containing white connective tissue fibers of a reactive fibrosis, secondary to the prolonged trauma of pivotal weight-bearing on a pointed condyle. Such a callus is often diagnosed as verruca plantaris and treated by irradiation, escharotics, electrodesiccation, or surgical excision of the mass. Many patients have been treated by all of these methods. The mass of scar tissue resulting from each type of treatment has been greater than the original excrescence, with increased disability. A comparable but less disabling condition occurs under the head of the first metatarsal and is usually due to an anomalous or hypertrophied tibial hallux sesamoid. New growths are uncommon under the head of the fifth metatarsal, but minor callosities are common.

The plantar surface of the head of each metatarsal has two condylar projections. Those of the middle three metatarsals end in sharp points extending proximally (fig. 2*B*). The condyle on the fibular side is always the larger. Because depression of the anterior arch is nearly a universal malady of civilized man, these condyles assume full weight bearing function. During walking they bear an added pivotal backward thrust for a short period during each step. This thrust results in the condylar points gouging into the soft understructures. These projections vary in size and shape from one metatarsal to another and in different persons. The plantar condyles of these metatarsals may vary from a mere rudiment to a projection higher than any other weight bearing point under all the metatarsal heads and from a ball-like surface to a pinpoint (fig. 2*B* and 2*C*). The sharper and more projective the condylar points the more the person is subject to fibrotic changes in the skin and subcutaneous tissue of this area. The skin under such a condyle accumulates horny cells as a protective measure, and a vicious cycle is produced: the greater the accumulation of horny layers the less space between the condylar surface and contact area, resulting in further compression of the soft tissues covering these areas and their gradual degeneration.

From the Department of Surgery, Columbus Hospital.

Because of lack of space, some of the figures and reports of cases have been omitted from THE JOURNAL and will appear in the author's reprints.

TREATMENT

In the past four years, I have excised 23 plantar condyles of the metatarsal heads of 21 patients, aged 23 to 62 years, with intractable growths immediately under the head concerned. There was complete relief in the majority of cases and marked improvement in all others. Fourteen (64%) of the patients were women. One woman and one man had growths bilaterally: in the woman the second metatarsal head of both feet were involved, whereas in the man the third metatarsal head of both feet were so afflicted. The second metatarsal head was involved in 12 cases (52%), the third in 8 cases (34%), and the fourth in 3 cases (13%). Three of the patients had had no previous treatment, five had had electrodesiccation and escharotics, four had had electrodesiccation, escharotics, and radiation therapy, three had had just radiation therapy, two just escharotics, two electrodesiccation, escharotics, radiation therapy, and excision, and one each just excision and electrodesiccation only.

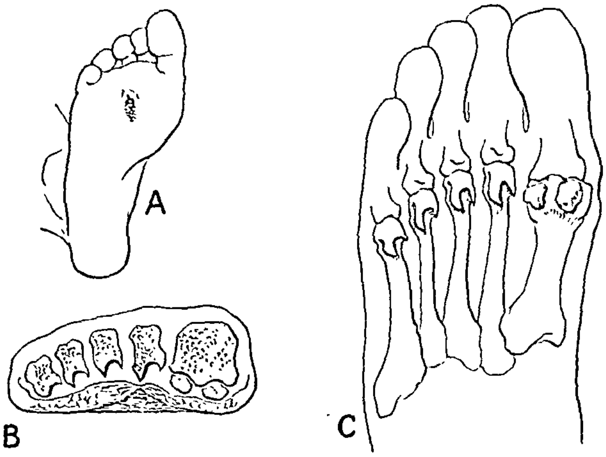

Fig. 2.—Location of verruca plantaris in plantar area. *A*, usual appearance of a new growth or scar under a metatarsal head. *B*, cross section of metatarsal head 0.5 cm. behind articular surface, showing condylar process. *C*, plantar view of metatarsal heads. Note that the fibular condylar process is normally the larger.

An incision is made immediately over the involved metatarsal phalangeal joint. The skin and extensor tendon are retracted, and the capsule is incised longitudinally (fig. 3). The capsule is then retracted with the skin margins, and a vertical incision is made in each side of the joint capsule (fig. 4); this frees the head of the metatarsal so that it can be delivered dorsally. The involved toe is plantar-flexed by the thumb of the surgeon's left hand, while the index finger of the same hand is applying pressure on the plantar surface of the metatarsal. This delivers the head of the metatarsal out of the wound (fig. 5). The plantar condyle is now amputated (fig. 6), and the surface is smoothed and rounded with a Joseph nasal rasp (fig. 7*A*). The capsule is closed with interrupted sutures (fig. 7*B*), and the skin margins are sutured.

REPORT OF CASES

Case 1.—The patient was a 54-year-old white male barber. For 10 years he had had a callus under the head of each third metatarsal. About seven years ago the condition was diagnosed as verruca plantaris, and electrodesiccation was employed, without relief. Two years later the growths were irradiated. Increase in size of the growths and resultant disability compelled the patient to give up barbering in 1950, because of inability to stand. Physical examination and routine laboratory findings were normal. In September, 1950, I removed the plantar condyles immediately over the growths. The patient was able to return to work, practice his trade two months later, and is to this day free from pain.

Case 2.—A 32-year-old white female waitress, in the spring of 1950, noted a growth under the second right metatarsal head, which was painful on weight bearing. The mass was diagnosed as verruca plantaris and excised. It recurred soon after healing of the wound. Some months later it was treated by electrodesiccation; again it recurred, more painful than ever. This was followed by many attempts to destroy the growths by escharotics. She first came under my care Sept. 8, 1952, with the complaint of inability to retain employment because she was unable to bear weight on the ball of her right foot.

On examination I found a cicatrix 2.5 by 1 cm. under the head of the right second metatarsal, whose center contained papillary formation resembling verruca tissue surrounded by scar (fig. 8). The mass was not adherent but penetrated the subcutaneous tissue and fascia. Results of routine physical examination and usual laboratory tests were normal. On Sept. 29, 1952, the plantar condylar surface of the second right metatarsal head was excised. The patient made an uneventful recovery and was able to bear weight comfortably on the ball of her right foot three weeks postoperatively. Since then the mass has almost disappeared (fig. 9), and she is completely free of pain.

SUMMARY

Verruca plantaris (plantar wart) and deep-seated calluses occur commonly under the metatarsal heads and often become a major disabling problem. Prevailing treatment often leaves disabling residual scar, and the radical procedures performed on intractable cases produce deformity. A new surgical approach to alleviate this malady is outlined. Twenty-one cases that have been successfully treated by this procedure are recorded.

CLARIFICATION OF SYPHILITIC AND NONSYPHILITIC SERODIAGNOSTIC REACTIONS

Reuben L. Kahn, D.Sc., Ann Arbor, Mich.

In general practice, the following questions often arise in relation to syphilitic and nonsyphilitic serodiagnostic reactions: How is it possible for serum reactions employing lipid antigens apparently unrelated to Treponema pallidum to behave as though they were specifically associated with syphilis, indicated by the remarkable parallelism between serologic and clinical findings in this disease? How can these same serum reactions also behave as though they were totally unrelated to syphilis, as shown by instances of biologically false positive reactions in various nonsyphilitic situations? If a positive serodiagnostic reaction in syphilis indicates the existence of this disease, what is the meaning of a positive reaction in the absence of syphilis? To answer these questions, it will be necessary to examine the relationship between the serodiagnostic reaction and the more comprehensive universal serologic reaction.[1]

THE UNIVERSAL REACTION

Serodiagnostic reactions stem from the universal serologic reaction. The universal reaction is a lipid antigen-antibody precipitation reaction that has given positive results in all human beings and animals tested thus far. The results in different human beings are differentiated by serologic patterns. The serologic pattern of a given person in health is constant. In the presence of pathological conditions, the universal reaction undergoes intensification after an incubation period of about two weeks; on recovery, the reaction reverts to normal. Table 1 shows a universal reaction in a normal person. Seven serum dilutions, each made with sodium chloride solutions of seven different concentrations, were employed. After the serum was mixed with the lipid antigen, the precipitation results were observed prior to incubation and again after 4 and 24 hours' incubation at refrigerator temperature (5 C). The precipitation results listed in table 1 are shown in figure 1. A characteristic common to universal reactions in healthy persons is that little or no precipitation is noted without incubation of the serum-antigen mixture (first section of figure 1); precipitation, illustrated by the cross hatched areas, makes its appearance after 4 hours' incubation (second section of figure 1) and is usually intensified after 24 hours' incubation (third section of figure 1). (All the series of graphs in figures 2 and 3 have the same construction as that in figure 1.)

RELATIONSHIPS BETWEEN UNIVERSAL AND SERODIAGNOSTIC REACTIONS

The ten sets of graphs in figure 2 illustrate universal reactions in health, syphilis, leprosy (nodular form), malaria (vivax), and tuberculosis and the relationship between universal and serodiagnostic reactions. In health, precipitation may be weak, as in graph series 1, stronger, as in graph series 2, or stronger still. In syphilis (graph series 3 and 4), precipitation is noted without incubation, and the degree of precipitation is almost the same after incubation; the serologic pattern is distinctive and is based presumably on the interaction between particular lipids and homologous antibodies; hence the reaction is lipid-specific. In leprosy (nodular form), the tendency toward precipitation on the left side of each of three sections of graph series 5 is greater than that on the right side, and the universal reaction is also lipid-specific, the serologic pattern being distinctive, although different from that in syphilis. The pronounced precipitation in graph series 6 is believed to be due to concurrent disease; graph series 5 is believed to represent the typical pattern. In malaria and tuberculosis, the serologic patterns (graph series 7 to 10) are nondistinctive and are considered nonspecific intensification of precipitation that occurs with the serum of normal persons (noted in graph series 1 and 2).

L.: Serology with Lipid Antigen, with Special Reference to Kahn and Universal Reactions, Baltimore, Williams & Wilkins Company, 1950; (*b*) An Introduction to the Universal Serologic Reaction in Health and Disease, Cambridge, Mass., Harvard University Press, 1951; (*c*) Present Status of Universal Reaction in Health and Disease, Univ. Michigan M. Bull. **17**: 211-239 (July) 1951.

are the result of different lipid antigen-antibody reactivities. Thus, lipids S may be said to react with antibodies s in syphilis, lipids L with antibodies l in leprosy, and lipids M with antibodies m in malaria. These reactions between different lipids and homologous antibodies are not limited to a given test but apply to serodiagnostic tests in general, whether precipitation or complement fixation tests, since all such tests are based on lipid antigen-antibody reactions. Syphilitic and nonsyphilitic serodiagnostic reactions stem from the same biologically universal serologic response, as is evident in figure 2. This brings up the question of why it is that only the syphilitic reactions (and the related reactions in the treponemal diseases, yaws, pinta, and bejel[2]) are of clinical significance.

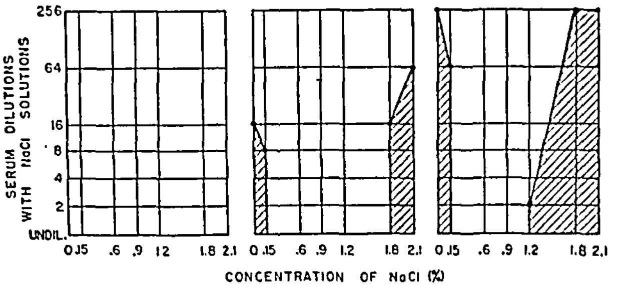

Fig. 1.—The plotting of the universal reaction precipitation results recorded in table 1. (This series of graphs forms the basis for those shown in figures 2 and 3.)

VALUE OF SERODIAGNOSTIC REACTIONS IN SYPHILIS

The clinical value of serodiagnostic reactions in syphilis is based on four factors: 1. In syphilis, as indicated, the serodiagnostic reaction is lipid-specific, the specificity being directed not against T. pallidum but against particular lipids set free presumably in pathological processes in this disease. 2. Since syphilis is a disease of moderate activity, high level antibody production is to be expected. Minimal activity and excessive activity are commonly forerunners of low antibody production. Malignant syphilis, accompanying excessive tissue breakdown, which was encountered years ago, generally led to negative serodiagnostic reactions. 3. Antibody production is continuous as a result of the chronic nature of the disease, and this leads to continuously positive serodiagnostic reactions. The serologic response in latent syphilis would indicate that subclinical syphilis processes in persons in whom the disease has existed for many years is sufficient for antibody production. The prolonged existence of an antibody-producing disease apparently results in a capacity for antibody production following minimal antigenic stimulation. In serologic fastness, the immunologic mechanism involved may be the same as that operative in the persistent positivity of the treponemal immobilization reaction (Moore and Mohr[3]) after adequate therapy in late syphilis. 4. The techniques of serodiagnostic testing are almost optimal for elicitation of positive reactions; for example, dilution or concentration of the lipids in standard Kahn antigen preparations will reduce their sensitivity to syphilitic serums.

These four factors apply also in the case of yaws, pinta, and bejel; hence, serodiagnostic reactions in these treponemal diseases have the same clinical value as they do in syphilis. These factors do not apply in leprosy, malaria, and tuberculosis. In many patients with leprosy disease activity is either minimal or excessive; only when it is moderate are conditions favorable for the occurrence of positive serodiagnostic reactions. In vivax malaria, conditions are not optimal for serodiagnostic detection of the disease; this is shown by the fact that, although universal reactions become intensified after febrile attacks, serodiagnostic reactions, as indicated in series 7 (fig. 2), may not become positive. In tuberculosis, serodiagnostic tests are not applicable; the reactions commonly remain negative even though universal reactions increase in intensity.

FALSE POSITIVE REACTIONS

The question arises why certain persons have false positive reactions in miscellaneous situations and others do not. The relationship between universal reactions and false positive serodiagnostic reactions is illustrated in figure 3. Persons who normally have universal reactions, illustrated in graph series 1 to 4, are not likely to become false positive reactors, because their lipid antigen-antibody reactivity is removed from the serodiagnostic zone. Those who normally have universal reactions, illustrated in graph series 5 to 8, are likely to become false positive reactors, because their reactivity is close to the serodiag-

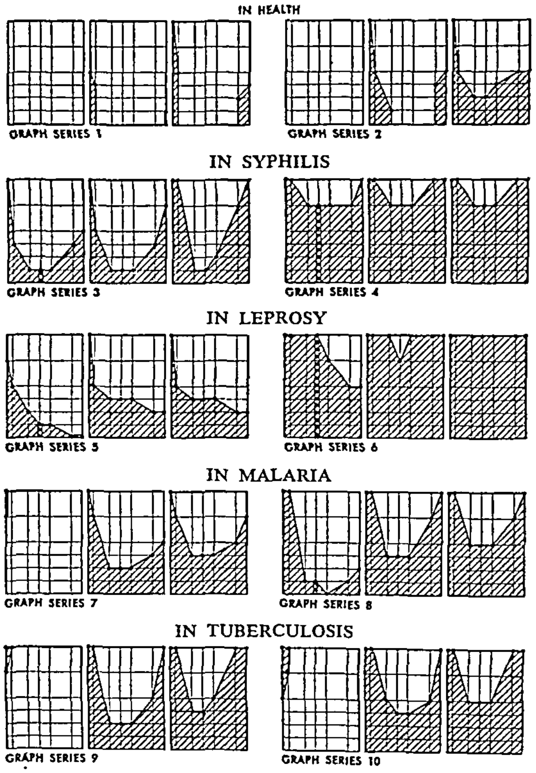

Fig. 2.—Universal reactions in health and disease, showing the relationship between universal and serodiagnostic reactions. (Each series of graphs represents the reaction of a different person.)

---

[2] Kahn, R. L., and Gutierrez-Villegas, L.: Universal Serologic Reaction in Pinta, Am. J. Syph. 36: 468-475 (Sept.) 1952. (This article considers also yaws and bejel.)

[3] Moore, J. E., and Mohr, C. F.: Biologically False Positive Serologic Tests for Syphilis: Type, Incidence, and Cause, J. A. M. A. 150: 467-473 (Oct. 4) 1952.

nostic zone; any condition that tends to increase this reactivity would lead to positive serodiagnostic reactions, such as those shown in graph series 9 and 10.

BASIS OF POSITIVE SERODIAGNOSTIC REACTIONS

The possible basis of positive serodiagnostic reactions has been suggested by the results of studies of the universal reaction. It has been observed that the latter reaction, present in health, is intensified in disease. The reaction is intensified also following irradiation [4] and following injection in animals of various substances as dissimilar as horse serum and paraffin oil.[5] This increase in intensity of the universal reaction indicates that the biological mechanism of *lipid antigen-antibody reactivity* has a common basis in tissue breakdown, ranging from that in normal catabolism to that in disease. The lipids thus liberated, it is believed, become foreign to the body and autoantigenic, as a result of chemical changes. Autoantibodies are then formed to these lipids that are detected in vitro by the universal reaction.

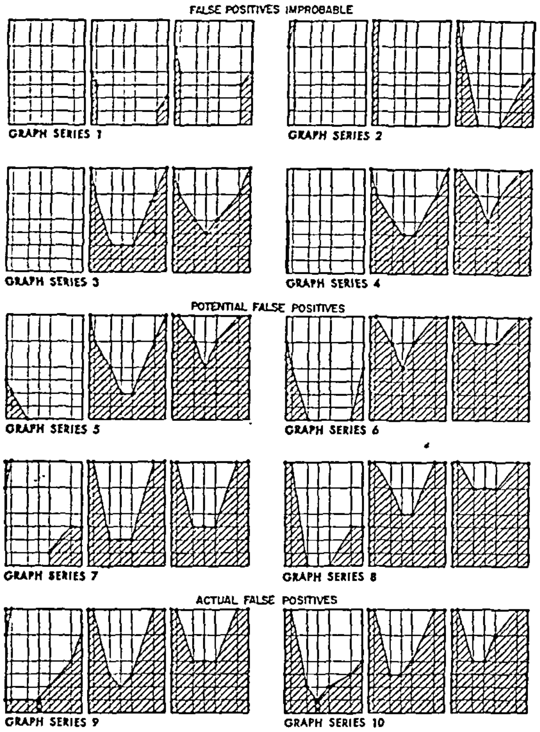

Fig. 3.—Universal reactions of nonsyphilitic persons as indicators of the varying tendencies of such persons to have false positive reactions. (Each series of graphs represents the reactions of a different person.)

In view of the relationship between serodiagnostic and universal reactions, the same concept should apply to both reactions. Accordingly, it is assumed that a positive serodiagnostic reaction, whether it occurs in syphilis, in nonsyphilitic diseases, following irradiation, or following injection of various substances, is the result of tissue breakdown or of increased tissue catabolism over the normal level and that the antibodies produced to the lipids liberated are of such a nature and concentration as *to be detectable by means of serodiagnostic tests.* This concept lends support to the clinical significance of positive serodiagnostic reactions in the absence of syphilis, suggested by me [6] and recently emphasized by Moore and Mohr.[3] False positive serodiagnostic reactions may be encountered (1) concurrently with pathological processes or increased tissue catabolism, (2) for weeks or several months after recovery, (3) prior to the appearance of clinical manifestations in diseases of prolonged onset,[7] and (4) in normal persons (rarely).

INCIDENCE OF FALSE POSITIVE REACTIONS

Because the impression may be gained from this article that false positive reactions in serodiagnostic tests are common occurrences, it should be emphasized that they are relatively rare. *This fact is indicated by the Kahn test* results reported from our laboratory in official serologic evaluation studies, based on the examination of given numbers of blood specimens from syphilitic and nonsyphilitic donors by various laboratories that were not advised of the clinical histories of the donors. Since 1937, the U. S. Public Health Service, aided by an advisory serologic council, has conducted 17 such evaluation studies, and in these not a single false positive or false doubtful Kahn reaction has been reported in the examination of 2,833 blood specimens from nonsyphilitic donors, as is indicated in table 2.[8] This specificity record of the Kahn test in official evaluation studies is reported not to suggest that this test is incapable of giving false positive reactions but to indicate that a serodiagnostic test, when performed correctly, may give results of high specificity.

SUMMARY

An attempt is made to clarify the behavior of serodiagnostic reactions employed in the diagnosis of syphilis, based largely on results obtained with the universal serologic reaction. These results have revealed a broad field of lipid antigen-antibody reactivities in health and disease and have thrown new light on the nature of serodiagnostic reactions, both in the presence and in the absence of syphilis.

SPECIAL ARTICLE

ON THE MECHANISM THROUGH WHICH HYDROCORTISONE AFFECTS THE RESISTANCE OF TISSUES TO INJURY

AN EXPERIMENTAL STUDY WITH THE GRANULOMA POUCH TECHNIQUE

Hans Selye, M.D., Ph.D., Montreal, Canada

THE JOURNAL *normally does not contain articles based on experiments performed on the lower animals. It is a clinical and an organizational journal; however, the following article by Dr. Hans Selye reports observations of clinical interest in a field that today is widely discussed. For this reason Dr. Selye's article is being published as a special article.*—ED.

In view of the manifold therapeutic effects of glucocorticoids, the mechanism through which they influence disease is of considerable interest to the physician. It is commonplace by now to say that they do not attack pathogens directly. Clinical observations led to the assumption that they might provide some "protective shield" around the tissues of the body, a barrier quite impermeable to many pathogens. This hypothesis would be consonant with the great nonspecificity of their protective effects, but it is hardly in keeping with the well-known fact that cortisone actually diminishes resistance to some aggressors (e. g., certain pathogenic micro-organisms). The purpose of this communication is to report on recent experiments that suggest an alternative interpretation that is compatible with the fact that these hormones can both protect and sensitize to various nonspecifically injurious agents (noxae).

As soon as the principal outlines of the general adaptation syndrome had been recognized, it became evident that close relationships exist between this "systemic stress response" and the topical phenomena of inflammation.[1] This view has since received ample confirmation.[2]

Firstly, both the general adaptation syndrome and inflammation represent nonspecific responses to a variety of apparently quite unrelated agents. However, while the former is elicited by systemic stressors, that is, by agents that affect the body as a whole, the latter is called forth by topical stressors, which affect only a limited area. Secondly, both the general adaptation syndrome and inflammation are triphasic types of reactions. The alarm reaction, the stage of resistance, and the stage of exhaustion in the general adaptation syndrome are respectively duplicated, in a sense, by the distinctly different reaction forms characteristic of acute inflammation, chronic inflammation, and the eventual breakdown of tissues (perforation of abscesses and necrosis). Thirdly, both in the general adaptation syndrome and in inflammation, certain pituitary and adrenal hormones (corticotropin [ACTH], somatotropin [STH], and corticoids) exert an important regulatory role. Fourthly, both the general adaptation syndrome and inflammation appear to be essentially useful defense reactions.

Whether inflammation is "useful" or "harmful" has been vigorously debated since the beginning of medical history (for an excellent review of this problem, see Bier [3]), and is still a controversial matter. My experimental studies suggested that this depends largely on the phlogistic agent under investigation. The suppression of inflammation by antiphlogistic hormones (e. g., corticotropin, cortisone, and hydrocortisone) or its augmentation by prophlogistic substances (e. g., somatotropin and desoxycorticosterone) can be useful or harmful, depending on the nature of the evocative irritant. Certain potential pathogens do not tend to cause local injury in themselves, nor do they induce systemic damage by spreading through the organism (e. g., egg white or dextran injected into the joint tissue of a rat). These agents cause lesions mainly because they elicit a marked phlogistic response. Hence, here suppression of inflammation by glucocorticoids is virtually synonymous with the suppression of detectable disease phenomena and is manifestly "useful." Conversely, in the case of agents that normally cause extensive local necrosis (e. g., croton oil or strong alkali), or tend to kill by dissemination and metastases (e. g., most pathogenic micro-organisms), the reverse is true. Here suppression of inflammation by glucocorticoids is usually harmful. Thus one may say that, although fundamentally inflammation is a defense reaction, it may itself produce morbid lesions if its development is not proportionate to the requirements induced by the evocative pathogen.

The corresponding protective value of the general adaptation syndrome with its counterpart, the potentially pathogenic effect of its derangements, has been discussed from this point of view in a series of earlier monographs [4] and hence requires no further comment here.

In the present communication I wish to report on a systematic experimental analysis of the above-mentioned defensive effect of inflammation with its corollary, the pathogenicity of derangements in the inflammatory potential of the body. For these investigations I employed the "granuloma pouch" technique, because it permits the

performance of quantitative function tests that help to assess the delimiting power of granulomatous tissue.[5]

As a moderator of the inflammatory reaction against a given irritant, I employed hydrocortisone, because, as far as is known at present, this is the most important natural antiphlogistic corticoid. Hence, it was thought that the data obtained with this hormone might help to clarify not only the functional value of inflamed tissue but also the mechanism through which endogenous corticoids could affect disease.

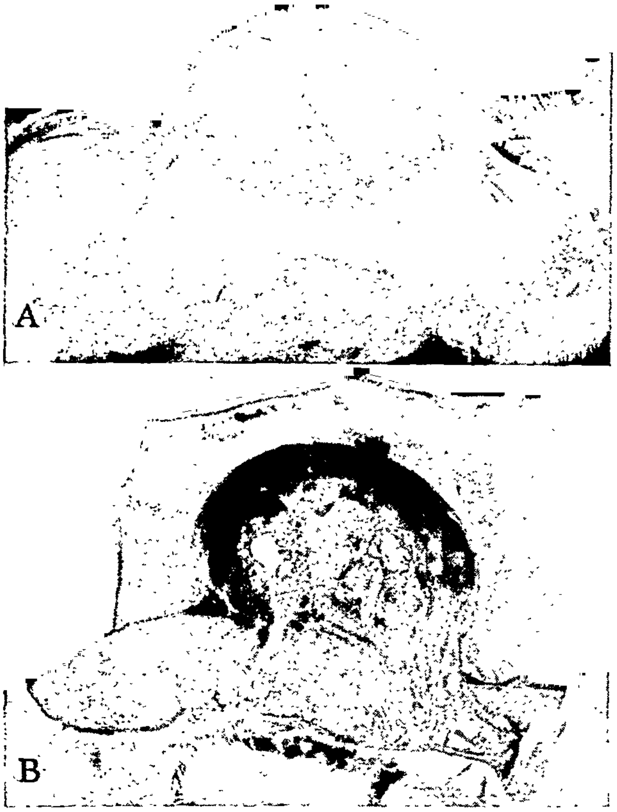

Fig. 1.—Dissection of the granuloma pouch. *A*, appearance of a fully formed granuloma pouch, as viewed from the outside. *B*, after the surrounding skin area was demarcated by a semicircular incision, the covering skin flap was dissected and turned back, exposing the cutaneous muscle layer whose fibers originate from the axillary region and then fan out over the entire granuloma pouch area.

EXPERIMENTAL TECHNIQUES

The granuloma pouch technique is a procedure designed to permit the objective, quantitative analysis of factors regulating inflammation and wound-healing. It is based on the observation that an almost perfectly symmetrical, ellipsoid air space of any desired size can be created by injecting a given amount of air into the loose subcutaneous connective tissue of the rat. The cavity thus formed acts as a "mold" for the subsequent formation of a granulomatous membrane, into which its entire inner surface can be transformed by the injection of an irritant (e.g., croton oil) into the air space itself. Through the selection of appropriate irritants it is even possible—within certain limits—to determine at will both the thickness and the structure of the resulting granulomatous membrane as well as the quantity and cellular constitution of the fluid exudate that gradually replaces the air.

A brief outline of this technique, with a few examples of its principal applications in the study of wound-healing and inflammation, have been given elsewhere.[6] Let me point out here, however, that in devising a test for the quantitative assessment of the protection given by inflamed tissue, my main concern had to be the enforcement of a consistent regular anatomic disposition, relative to each other, of (1) the pathogen (croton oil), (2) the barrier (granuloma membrane), and (3) some target or indicator of tissue penetration (skin). Numerous dissection preparations of granuloma pouches showed that the invariable topographic relationships of this structure fulfill the above requirement (fig. 1 and 2). This is particularly important for studies aiming at a differentiation between inflammation and necrosis. It had long been known that irritants can elicit both these reaction types and that cortisone, though usually a "protector of tissues against injury," may occasionally facilitate the production of necrosis (e.g., in the lung, liver or kidneys).[4a] In most of the spontaneous or experimental diseases, however, the special relationships between pathogen, barrier, and target are so variable and irregular that the resulting lesions do not lend themselves to a precise analysis of their pathogenesis.

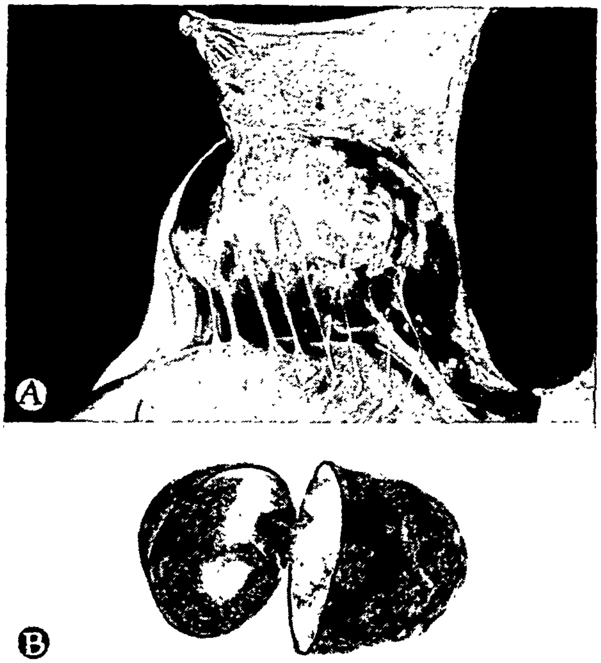

Fig. 2.—Further steps in dissection of the granuloma pouch. *A*, the skin muscle has been dissected and lifted up to show its relation to the actual granuloma membrane, which is covered by it just underneath the skin. Some of these muscle bands remained attached to the fascial layers of the back, so that the pouch actually developed within two laminas of the cutaneous musculature. The neurovascular pedicles of the pouch are clearly visible, as cords emerging from each of the intercostal spaces and ascending vertically towards the granuloma in which they distribute themselves. *B*, after enucleation and fixation, the granuloma pouch was opened by an almost complete frontal section. The even thickness and the great regularity of the external and internal surfaces can be noted.

It is also noteworthy, in connection with the observations reported here, that both the membrane and the exudate of the granuloma pouch are highly sensitive to the action of so-called adaptive hormones of the pituitary and adrenal. Thus, minute doses of hydrocortisone, especially if injected directly into the wall of the pouch, suffice to inhibit the formation of both a granulomatous membrane and an exudate, while somatotropin exerts opposite effects.[5]

The granuloma pouch technique also proved useful in elucidating the phenomenon of "induced topical resistance" to acute tissue injury. In essence, it has been found that if, as a result of contact with a weak irritant (e. g., dilute croton oil), an inflammatory response develops along the inner surface of such a connective tissue sac, the wall becomes highly resistant, even to otherwise necrotizing doses of intensely injurious substances (e. g., concentrated croton oil). At the same time the resistant granulomatous membrane effectively protects adjacent tissues (for instance the skin that covers it) from the chemical irritant. Interestingly, the inhibition in the morphological development of the granuloma by topical hydrocortisone treatment is paralleled by a diminution in this "induced topical resistance." [7]

Effect of Pretreatment with Irritants and/or Hydrocortisone on Resistance to Concentrated Croton Oil

Groups	Pretreatment 1st Day	 5th Day	 9th Day	Thickness of Granuloma, μ *	Treatment 10th Day	Necrosis of Skin Incidence, %	 Extent, % of Surface

* Figures in this column represent the average of five measurements made on each of the two rats that were killed on the 10th day, just prior to the injection of concentrated croton oil. Measurements were made only on the peripheral wall of the granuloma pouch, i.e., the portion adherent to the skin. The total width, as expressed here, corresponds to the total inflamed area. In many instances, this exceeds the limit of the dissectable granuloma membrane, since portions of the skin outside this structure may also be infiltrated by inflammatory cells. The salient histological features of these tissues are described in the legends of figures 4 and 5.

In the present study, I used this technique primarily to clarify concepts concerning the mechanism through which a topical inflammatory response can protect the adjacent tissues as well as the body as a whole. For this purpose the test was performed as follows: First, the hair was removed over the entire dorsal region with fine electric clippers. Then 25 ml. of air was injected into the loose connective tissue, between the shoulder blades, through a no. 27 hypodermic needle. This was immediately followed by the injection of 0.5 ml. of an 0.5% croton oil solution (in corn oil) into the resulting air space.

In order to do this accurately, yet with the least amount of injury to the skin, the air was first injected with a large syringe. This was then detached from the needle, which was left in situ for the subsequent injection of the croton oil, through an accurately calibrated small Luer-Lok syringe. The accumulation of the hemorrhagic inflammatory exudate (usually produced by croton oil) could readily be followed from day to day by transillumination of the transparent skin pouch with a strong flashlight. Significant amounts of this fluid began to be detectable in the cavity of the pouch around the fourth to fifth day of the experiment. The shape and volume of the connective tissue cavity exposed to the croton oil was kept virtually identical by the air "mold"; hence, the response proved to be essentially of the same intensity in all animals.

On the fifth day, a second injection, this time of 0.5 ml. of a 3% croton oil solution (in corn oil), was administered into the cavity of the by now well-formed granuloma pouch. Since the first injection induces the above-mentioned phenomenon of topical resistance, there is no danger of producing skin necrosis over the pouch by the subsequently given stronger irritant.

In one type of control experiment, the same procedure was followed but, instead of the croton oil solutions, pure corn oil (0.5 ml.) was injected on the first and fifth day. Other control animals received only 25 ml. of air, to produce a connective tissue cavity with no oily material.

Hydrocortisone was administered in the form of a microcrystal suspension containing 25 mg. per milliliter.* In some experiments this was injected directly into the cavity of the pouch and in others into its wall. For the latter purpose, the total dose was given in the form of two separate but simultaneous injections of 0.1 ml. each, just below the skin surface near the caudal pole of the air sac, into the connective tissue that was later to transform itself into the granulomatous membrane. Seven experimental groups, each consisting of 10 female Wistar albino rats with an average body weight of 130 gm. (range 115 to 147 gm.), were treated as outlined in the table.

It will be noted that the pretreatment procedure varied; however, on the 10th day, in all groups concentrated croton oil (0.5 ml.) was injected into the air space, so as to determine the resistance of the surrounding skin to the necrotizing action of this strong irritant.

[7] Selye, H.: Induction of Topical Resistance to Acute Tissue Injury (An Experimental Study with Granuloma Pouch Technique), Surg. Clin. North America, to be published.

* Supplied by Merck and Company, Montreal, Canada.

In groups 1 to 5, the cavity was formed by the subcutaneous injection of air (25 ml.), on the first day, and in groups 6 and 7 on the ninth day. In groups 1 and 3, corn oil (0.5 ml.) was injected into the cavity on the first and fifth day, while in groups 2 and 4, increasing concentrations of dilute croton oil were administered on the first day (0.5%) and fifth day (3%) in the same volume. The animals of groups 1 and 2 received no additional treatment, while those of groups 3 and 4 were also given 5 mg. of hydrocortisone into the granuloma wall on the first day of the experiment. This made it possible to assess the effect of hydrocortisone on the pretreatment value of a very mild (corn oil) and an extremely strong phlogistic agent (croton oil), by comparing group 1 with group 3 and group 2 with group 4 respectively.

It had been noted earlier that a given dose of hydrocortisone inhibits inflammation much more effectively if it is incorporated into the granuloma wall than if it is introduced into the cavity of the pouch.[5] In the present study, however, my primary interest was to determine the effect of this hormone on the necrotizing actions of a strong irritant. Hence, it was deemed necessary also to include animals in which hydrocortisone is injected directly into the pouch cavity. This was done in group 5, but, because absorption by this route is very rapid, three injections of 5 mg. each were given on the 1st, 5th, and 10th days.

In group 6, a still larger dose (12.5 mg.) of hydrocortisone was introduced directly into the cavity of a freshly prepared air sac on the ninth day, i. e., just 24 hours before exposure to concentrated croton oil. In group 7, an air space was also prepared on the ninth day, but no hormone was introduced into its cavity. By comparing groups 6 and 7 I wanted to assess the possible effect on necrosis of heavy, but brief, pretreatment with hydrocortisone alone.

On the 10th day, two rats in each group were killed in order to obtain a first histological specimen of the tissues lining the air space just before the introduction of the necrotizing concentrated croton oil solution. The specimens were always taken from the lateral border of the pouch (along the line of transition between the normal adherent skin and that detached by the air space). Susa solution was used as a fixative, and paraffin sections were stained with hematoxylin and eosin.

Forty-eight hours after the injection of concentrated croton oil, that is, on the 12th day of the experiment, all animals were killed and the incidence of skin necrosis was registered irrespective of the extent of the necrotic skin areas. In the table this is expressed as the percentage of animals with necrosis in terms of the total number within each group. It will be seen from the table that these readings gave comparatively little information, since all the animals in all the groups except group 2 had some degree of cutaneous necrosis, making the incidence 100%.

Much more could be learned from the determination of the extent of skin necrosis. Owing to the extremely regular and reproducible anatomic relationships between the granuloma pouch and the skin, the peripheral part of the former is always directly attached to the latter everywhere. In other words, every point of the surrounding cutaneous surface is separated from the irritant by an even granulomatous barricade, which is intimately applied to it. Hence, in all animals in which only part of the skin underwent necrosis, the affected area could be accurately measured and objectively expressed as a percentage of the total skin area that covers the pouch. It should be mentioned that the necrotic skin regions assume a purplish-gray color and are sharply separated from healthy skin by a distinct narrow red line of reactive hyperemia.

To measure these necrotic areas exactly, the entire skin of the back was removed, dissected, and spread on a wooden board. The elliptic outline of the skin adherent to the pouch is somewhat elevated, because of the underlying granulomatous membrane. To bring it out even more clearly this raised border line was traced with a grease pencil. With a planimeter, first the total adherent skin area was measured and then the surface of the necrotic area (or areas) was determined, by following the red hyperemic line of demarcation. Thus, the percentage of the skin surface that underwent necrosis (with its standard error) could be objectively established in all groups (fig. 3). Finally, a second histological specimen of the skin and the underlying granulomatous membrane was taken, again from the lateral aspects of each pouch, for examination of the tissues after exposure to concentrated croton oil.

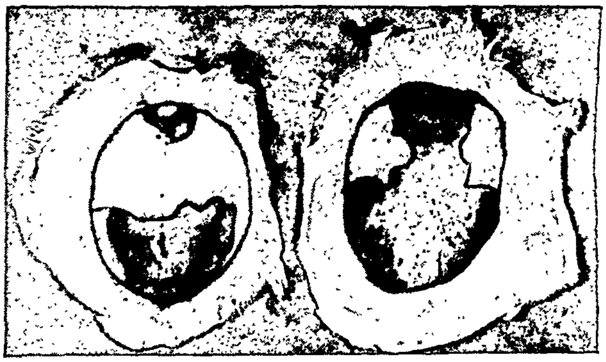

Fig. 3.—Examples of skin specimens prepared for planimetric measurements. The necrotic (dark) zones are clearly distinguishable from the living (light) portions. Measurements on these two samples showed that in the animal on the left 40% and in that on the right 73% of the total adherent skin area had become necrotic.

EXPERIMENTAL RESULTS

The results of all these experiments are summarized in the table, while the morphological basis of the observed changes is illustrated in figures 4 and 5. These data reveal the following facts:

1. Even pretreatment with such a comparatively innocuous substance as corn oil induces some topical resistance to concentrated croton oil. This is revealed by a comparison of the extent of necrosis in groups 1 and 7 (P less than 0.01).

2. Pretreatment with gradually increasing doses of croton oil produces the greatest topical resistance so far observed. This is presumably due to the fact that croton oil elicits very intense granuloma formation. This is evidenced by a comparison of group 2 with any of the other groups. It will be noted that only in group 2 were all animals free of any trace of necrosis.

3. Hydrocortisone, administered into the wall of the pouch, greatly diminishes the topical acquired resistance

normally induced by corn oil pretreatment. This is shown by a comparison of the extent of necrosis in groups 1 and 3 (P less than 0.01). Presumably the hormone acts by inhibiting the formation of a limiting connective tissue barrier around the oil deposit.

4. Hydrocortisone, administered into the wall of the pouch, also reduces the normally considerable resistance induced by pretreatment with gradually increasing doses of croton oil. This is evidenced by a comparison of the extent of necrosis in groups 2 and 4 (P less than 0.01). The suppression of topical resistance that is thus induced is presumably due to the fact that the hormone greatly diminishes granuloma formation even around this strong irritant. It remains to be seen whether the thin granulomatous membrane that is elicited by irritants despite hydrocortisone treatment differs qualitatively (as regards its functional value) from ordinary granulomatous tissue of equal thickness.

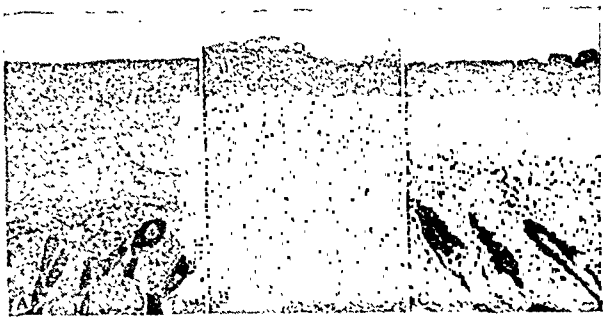

Fig. 4.—Histological effect of pretreatment with irritants and/or hydrocortisone of the pouch wall just prior to the final exposure to concentrated croton oil.

5. Repeated intense overdosage with hydrocortisone administered into the pouch cavity also inhibits the acquired topical resistance that is normally induced by croton oil. Indeed, under the conditions of these experiments, the inhibition so induced was even more pronounced than that caused by a smaller single dose of the hormone, given into the pouch wall. This is shown by a comparison of the extent of necrosis in groups 4 and 5 (P less than 0.01).

6. Intense but brief pretreatment with hydrocortisone, administered into the pouch cavity, fails to protect against the necrotizing action of concentrated croton oil, as shown by a comparison of groups 6 and 7 (P more than 0.5). Since in both of these groups, however, more than 96% of the skin area had become necrotic, I wondered whether the lack of difference between them might not be due merely to the severity of the resulting damage, which made the tissues insensitive to hormonal stimuli.

For this reason, an additional small experiment was performed under exactly the same conditions, but using 0.5 ml. of a 10% croton oil solution on the 10th day. In one group of 10, otherwise untreated, control rats, this caused necrosis, with an incidence of 90% and an extent of 39.7% (± 8.7). In a second group of 10 rats that received 12.5 mg. of hydrocortisone on the day preceding the introduction of the 10% croton oil, the incidence of necrosis was 100% and its average extent 63% (± 7). Because of the great standard error in both groups, this difference was not quite significant (P = 0.07). Yet, in any event, it is obvious that the hydrocortisone did not protect; indeed, if it had any effect, it sensitized the skin to the necrotizing action of our irritant. Since in this short-term experiment there was no time for the croton oil to produce a protective granuloma, it was to be expected that here the sensitization by hydrocortisone (which depends on the inhibition of granuloma formation) could not be pronounced.

The histological effect of pretreatment with irritants and/or hydrocortisone of the pouch wall just prior to the final exposure to concentrated croton oil is shown in figures 4 and 5. All of the specimens were taken from the peripheral walls of the pouches, where the granuloma is directly in contact with the skin. The tissues are so oriented that the air space with the lining granuloma membrane is near the upper and the skin near the lower margin of the photographs. In group 1 (fig. 4*A*) after pretreatment with corn oil alone, the granuloma consisted of small roundish epithelioid-looking cells with narrow capillaries. There is no necrosis or leukocytic infiltration. The connective tissue fibers and cells are arranged in concentric layers around the cavity. Below the granulomatous membrane, the cutaneous muscle is intact. Still further down, the normal adipose tissue and hair follicles of the skin are noted (average width 250 μ). In group 2 (fig. 4*B*) after pretreatment with gradually increasing doses of dilute croton oil, an extremely thick granulomatous membrane developed, consisting of large elongated cells and wide capillaries. Along the inner surface there is much necrotic material, intermixed with pus. The muscle is also intensely infiltrated by the granuloma; only a few muscle fibers are still distinguishable along the lower margin of the field. The fibroblasts and capillaries of the inner granuloma layers tend to be radially arranged ("palisade formation"), though some of them are rather irregularly interlacing. This picture is quite characteristic of granulomas that have acquired considerable resistance to irritation. (The average width of 900 μ exceeded the photographed area.) In group 3 (fig. 4*C*) the simultaneous pretreatment with corn oil and hydrocortisone produced a histological picture that is qualitatively similar to that seen in figure 4*A* (i.e., without treatment with hydrocortisone), but the lining membrane is much thinner (average width 80 μ).

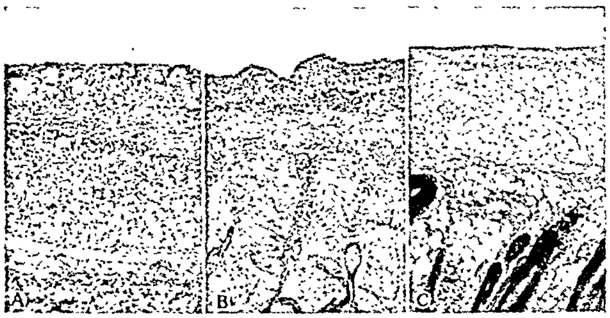

Fig. 5.—Histological effect of pretreatment with irritants and/or hydrocortisone of the pouch wall just prior to the final exposure to concentrated croton oil.

Figure 5*A* shows the result of simultaneous pretreatment with croton oil and hydrocortisone in group 4. The granuloma is not unlike that seen in figure 4*B* but is considerably reduced in thickness. It consists of medium-sized but rather elongated spindle-shaped cells, which are more or less irregularly interlacing although many of them are radially arranged, as are the capillaries between them. There is no necrosis and very little infiltration with polymorphonuclear leukocytes along with free border, but there is a fairly thick layer of intensely dilated capillaries. In the upper part of this field these assume a capillary-hemangioma-like appearance. The cutaneous muscle is partially infiltrated by fibroblasts (average width 300 μ). Figure *5B* shows the result of simultaneous pretreatment in group 5 with corn oil and repeated administration of hydrocortisone (in this case injected into the cavity of the air sac). There is no inflammatory reaction, but there is a beginning surface organization in the sense that the fibroblasts normally lining the air space are more closely packed and more regular than in the following two groups (represented by fig. *5B*), in which the connective tissue was not exposed to any irritating pretreatment. A single photograph (fig. *5C*) is given to illustrate the changes in both groups 6 and 7, since their tissues were histologically indistinguishable. In all these rats, whether they were pretreated with air and cortisone (group 6) or with air alone (group 7), there was no inflammatory reaction and no trace of surface organization. The inner lining consists merely of irregular, partly necrotic or degenerating, fibroblasts and fibers. Some of these are detached and in the process of being cast into the cavity. The picture resembles that of a freshly produced connective tissue wound in which no reaction has set in as yet. Since in these two groups there was no inflammation, it was not possible to measure the thickness of any actual granuloma membrane.

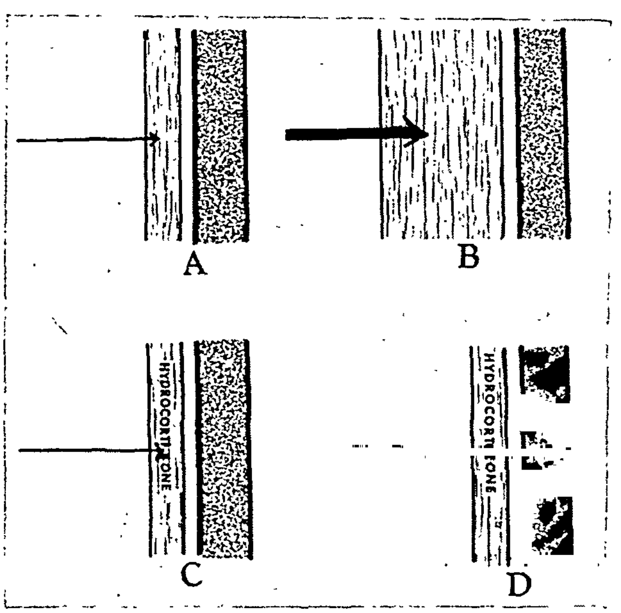

Fig. 6.—Schematic drawing illustrating probable mechanism of hydrocortisone action in tissues endangered by irritants. *A*, mild preliminary irritation (thin arrow) acting upon connective tissue (streaky area) but not penetrating to adjacent skin (dotted area). *B*, great increase in connective tissue due to granuloma formation by previous exposure to mild irritant. Subsequently applied strong irritant (heavy arrow) is now well tolerated by the adjacent skin, due to the protective effect of the granuloma. *C* and *D*, hydrocortisone "protects" connective tissue from being transformed into an effective thick granuloma and, hence, subsequent exposure to the strong irritant results in necrosis (black areas) of the adjacent tissue.

COMMENT

From these experiments I am inclined to deduce first of all that, although necrosis frequently accompanies severe inflammatory reactions, the two are essentially distinct phenomena that can be experimentally separated from each other. Indeed, in a sense, there is a significant negative correlation between them. The more an irritant stimulates inflammation the better are the adjacent tissues protected against necrosis and, conversely, selective inhibition of inflammation (e.g., by an antiphlogistic corticoid, such as hydrocortisone) facilitates the production of necrosis. Presumably inflammation is a natural defense mechanism against potentially damaging (e.g., necrotizing) agents. In the light of these findings, the commonly used term "necrotizing inflammation" would appear to be misleading. It is not the inflammation that is "necrotizing" but those histotoxic agents that are unable to induce a degree of inflammation sufficient to protect the tissues against their own necrotizing effects. The observation that an antiphlogistic corticoid exerts diametrically opposite effects on the phlogistic and necrotizing actions of the same pathogen (croton oil) is, in my opinion, of import in the interpretation of disease phenomena in general.

It will be recalled that the beneficial action of cortisone and cognate hormones was at first thought to be more or less specific for rheumatic and allied "collagen diseases." Subsequently, when the therapeutic spectrum of these substances was found to be wider than expected, the hypothesis was advanced that these corticoids act by creating some "shield-like buffer against the various irritants," [8] which prevents the pathogen from injuring the body tissues. The fact that, through some effect on the hyaluronidase-hyaluronic-acid system, glucocorticoids inhibit spreading through connective tissue appeared to give support to this contention.[9]

Conversely, earlier work led me to suspect that the most characteristic defensive action of these hormones depends precisely on their great efficacy in destroying barriers between pathogen and host, by depressing the "inflammatory potential." Hence, I thought of them as primarily "antiphlogistic corticoids." [10]

It is in order to further elucidate this point that I undertook the experiments reported in this paper. Hence, I purposely selected a pathogen (croton oil) that has both phlogistic and necrotizing properties. The effect of hydrocortisone on the reaction to this irritant was then examined under various conditions to determine whether both actions are always concurrently blocked, as postulated by the cell-shield hypothesis. The data obtained clearly demonstrate that this is not the case. The hormone does not protect against the pathogen as such (e.g., by putting some impenetrable separation between it and the tissues or by making the cells insensitive to it); it prevents only the strictly inflammatory response. This effect would be useful, in the case of pathogens that, like most allergens, are not very injurious in themselves and whose damaging action is mainly due to their phlogistic effects. Yet, it can also be harmful if, as in the case of croton oil, the pathogen causes severe injuries on contact with the

tissues, injuries that could be prevented by the erection of a granulomatous barricade. The principle of this hormone action is illustrated by the diagrams (fig. 6).

One could still argue, of course, that hydrocortisone places a barrier between the pathogen and the connective tissue, thus preventing the latter from turning into a granuloma. This would leave unexplained how the pathogen can nevertheless penetrate and destroy this same connective tissue to reach an adjacent target in the skin in my experiments (fig. 6*D*).

It may be questioned whether animal experiments such as these can be considered suitable models on which to study the mechanism of corticoid actions in general. If they are, however, it would appear unjustified to persist in postulating that antiphlogistic corticoids place an impenetrable barrier—an "asbestos suit"[11]—between the potential pathogen and the sensitive, living tissues. On the contrary, they act mainly by interfering with the development of the granulomatous barriers, whose chief vital function is to effect such a separation.

SUMMARY AND CONCLUSIONS

The technique for the production of a "granuloma pouch" in the rat has been described in detail and the morphological configuration of this structure has been analyzed with the help of anatomic dissections. Function tests were performed on granuloma tissue with the aid of this technique. In particular, it was found possible to assess—by objective planimetric measurements of skin necroses—the value of inflamed subcutaneous tissue as a protective barrier against toxic chemical irritants such as croton oil. Like most substances that are highly irritating to tissues, croton oil causes a so-called necrotizing inflammation. With the granuloma pouch technique, it has been shown that the two components of this allegedly single response (necrosis and inflammation) can be separated. Suitable treatment with an antiphlogistic corticoid, such as hydrocortisone, selectively inhibits the phlogistic effect of croton oil without impeding its necrotizing actions. Indeed, in normal and hydrocortisone-treated rats, there appears to exist an inverse proportion between the development of an inflammatory barrier around an irritant and the tendency of adjacent tissues to undergo necrosis. On the basis of these experiments, the hypothesis is elaborated that inflammation and necrosis are two related, but fundamentally opposed, types of reactions to nonspecific tissue injury; the former is progressive and protective and the latter regressive and due to inadequate protection in the face of aggression. These findings are incompatible with the rather widely held view that hydrocortisone and allied compounds act by placing some protective barrier around the cells that shields them against potential pathogens. Since these hormones can inhibit one action (inflammation) while aggravating another effect (necrosis) of the same agent, they cannot be visualized as mere insulators of cells against pathogens. On the contrary, the principal action of these steroids appears to be that they inhibit the development of granulomatous barriers between irritants and vital tissues.

Case Postale 6128.

CLINICAL NOTES

CURE OF SUBPHRENIC ABSCESS WITH LARGE DOSES OF OXYTETRACYCLINE (TERRAMYCIN)

Jerry Zaslow, M.D.
and
Fred Sachs, M.D., Philadelphia

"Conservative treatment of subphrenic infection should be given a trial unless the clinical manifestations and the radiological investigations indicate or strongly suggest abscess formation. . . . In many instances these measures will succeed and an abscess may thus be aborted, the fever subsiding in a few days, the pain and tenderness diminishing, and the convalescence from the original causative lesion or operation being resumed. . . . If the characteristic clinical picture of subphrenic infection continues unabated for three to six days, it is wiser to operate than to temporize indefinitely with medical measures. Operative treatment should be carried out immediately as soon as the subphrenic abscess is diagnosed or suspected."

The foregoing statements are taken from the book "Abdominal Operations" by Rodney Maingot,[1] and they reflect the opinions of teachers of surgery today. Once the diagnosis of a subphrenic abscess has been established, the importance of immediate operation to evacuate the abscess is emphasized. Ochsner and DeBakey[2] found that of 1,096 patients not operated on there were 985 (89.8%) deaths, whereas of 1,492 patients in whom operation was performed there were 637 (32.8%) deaths. Ochsner and Graves[3] demonstrated that the death rate was much higher when there was an associated thoracic complication. These figures were found in the prechemotherapeutic era. After reviewing the recent literature we have been unable to find what effect chemotherapy and antibiotics have had on these figures; however, we believe that the prophylactic use of these agents has reduced the incidence of these infections, and in those cases where infection does start in the subphrenic spaces it is often aborted before it reaches frank suppuration.

Abscesses in other portions of the body have been treated with antibiotics, on occasion with complete resolution of the process. The classical report by Crile[4] in treating appendiceal abscesses with penicillin is an example. Generally, the antibiotics have not replaced surgical drainage of such infections, but have merely helped localize these infections, simplifying the operative procedure and making the patients better operative risks. The following report is of interest because it represents

a postoperative subphrenic abscess that was treated with large doses of oxytetracycline (Terramycin), resulting in complete resolution of the disease.

REPORT OF A CASE

A 42-year-old white man was admitted to the Albert Einstein Medical Center, Northern Division, Aug. 17, 1952, with a diagnosis of chronic calculous cholecystitis. A cholecystectomy and choledochostomy were performed on Aug. 18. At the completion of the procedure there was no evidence of bleeding; however, 12 hours after operation there was evidence of internal hemorrhage and the abdomen was reexplored. There was about 1,500 cc. of fresh blood in the peritoneal cavity. It was determined that the site of bleeding was from a small vein that had been incised during opening of the common bile duct. The blood was aspirated from the abdominal cavity and the bleeding vessel ligated. The immediate postoperative course was uneventful except for the development of a diffuse patchy atelectasis, which responded to medical measures. During the postoperative period the patient received 1 cc. of Combiotic (a penicillin-dihydrostreptomycin preparation) and 600,000 units of Crysticillin (a procaine penicillin G preparation) every 12 hours. The temperature, up to 103 F immediately after operation, gradually returned to normal by the fifth postoperative day (Aug. 24). On Aug. 25 antibiotic therapy was stopped. That afternoon diffuse abdominal craps and diarrhea developed; the temperature rose to 102.4 F and the pulse to 104 per minute. Antibiotics were given again, and the temperature promptly became normal. The diarrhea subsided on Aug. 26. Physical examination at this time was essentially negative. On Aug. 25 a postoperative cholangiogram and chest roentgenogram were done (fig. 1). Both were normal. In the early morning of Aug. 27 (eighth postoperative day) the patient appeared well. Quite suddenly later that morning the patient complained of severe pain in the right upper quadrant, right shoulder-top pain made worse by deep breathing, and dyspnea. The temperature rose to 102 F, the pulse to 120 per minute, and the respiratory rate to 32 per minute. Breath sounds were audible at both bases. There was marked tenderness and rigidity in the right upper quadrant of the abdomen. The remainder of the abdomen was soft and moderately distended; peristalsis was normal. The leukocyte count was 58,250 cells per cubic millimeter, of which 97% were polymorphonuclear leukocytes, many showing toxic granulation. X-ray examination done early that afternoon showed the chest to be normal, but air not seen on the film two days before was seen under the right diaphragm. The small intestine was moderately distended. The administration of Combiotic and Crysticillin was stopped. A Miller-Abbot tube was passed into the bowel, and intravenous administration of oxytetracycline, 1 gm. every 12 hours, was started. It was presumed at this time that we were dealing with an infection, perihepatic in location, not well localized, and associated with a small bowel paralytic ileus. A consultation by one of the other surgeons was requested. He felt that we should persist with the above measures, and, should an abscess develop, it should be drained. We all agreed that at this time there was no localization or abscess formation and that surgery was contraindicated.

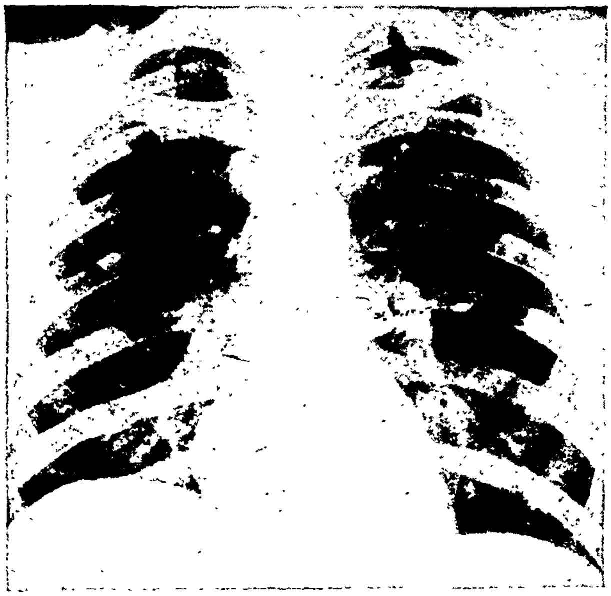

Fig. 1.—Chest roentgenogram taken on Aug. 25 showing normal lung fields, no effusion, and a sharp outline of the right side of the diaphragm.

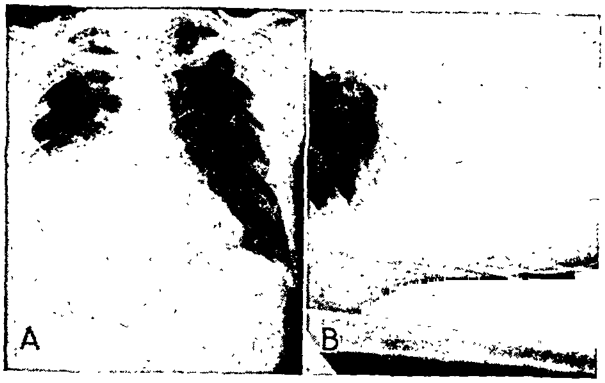

Fig. 2.—Chest roentgenogram showing subphrenic abscess. *A*, Sept. 2, showing a right pleural effusion, obliteration of the right costophrenic sulcus, air under the right side of the diaphragm, and obliteration of the normal shadow of the right side of the diaphragm. The right side of the diaphragm is elevated, and the hepatic shadow appears enlarged. *B*, Sept. 24, no air under the right side of the diaphragm. The effusion on the right appears to be decreasing.

Two days later (Aug. 29) the temperature had dropped to 100.6 F, the pulse rate to 100 per minute, and the respiratory rate to 28 per minute. There was less tenderness and pain in the right upper quadrant, but tenderness was present over the two lower right intercostal spaces. Deep breathing was still uncomfortable. There was suppression of breath sounds at the right base. An x-ray examination at this time demonstrated fluid in the right costophrenic sulcus with obliteration of the shadow of the diaphragm. The liver shadow appeared to be increased in size. A definite diagnosis of a subphrenic abscess was made. In view of the fact that the patient appeared to be improving clinically, no change in therapy was made. On Sept. 1 all local tenderness was gone, but breath sounds could not be heard below the angle of the right scapula. X-ray examinations were repeated every third day (fig. 2), and on Sept. 5 fluid was seen as high as the fifth rib posteriorly on the right side. The Miller-Abbott tube was removed seven days after its insertion when all signs of ileus disappeared.

During this entire period the temperature was gradually decreasing so that on Sept. 6 it had returned to normal. The leukocyte count fell to 26,800 cells per cubic millimeter on Aug. 30 and to 17,050 on Sept. 3. On Sept. 4 the intravenously administered oxytetracycline was discontinued and orally administered oxytetracycline was substituted in a dosage of 500 mg. every six hours. The patient left the hospital on Sept. 9, continuing with orally administered oxytetracycline. After one week the dosage of the drug was decreased to 250 mg. every six hours and finally none was given the following week. An x-ray examination 10 days after the patient's discharge showed a decrease in the amount of fluid in the right base and a decrease in the hepatic shadow and the absence of any air below the diaphragm. A final x-ray examination done on Nov. 1 showed complete resolution of the process as indicated by a normal chest film, no increase in the size of the liver shadow, and a sharp diaphragmatic shadow (fig. 3). Normal diaphragmatic movements were demonstrated by fluoroscopy.

COMMENT

On the eighth postoperative day the patient suddenly experienced dyspnea, severe right upper abdominal pain, and fever. It became apparent that a local inflammatory process was present. Whether there had been a subhepatic infected hematoma that had suddenly ruptured and produced a spreading peritonitis or whether organisms introduced at the time of cholangiography were responsible was difficult to determine. We felt that the former was probably the case and that the infection had been held in check by the penicillin and streptomycin given up to that time. It was also apparent to us that since this had happened in spite of the fact that these antibiotics were being given, they would probably be of little value in further treatment. Since one of us (J. Z.) has been having excellent results in the treatment of intra-abdominal infections with oxytetracycline in large doses, it was decided to administer this antibiotic at this time. While the response was not dramatic, it was apparent from daily observation that the patient was improving subjectively and that the temperature, leukocyte count, and local upper abdominal symptoms were decreasing. After 72 hours the tenderness was localized to the right subcostal area and the lower two right anterior intercostal spaces. Incision and drainage at this time was considered, but in view of the fact that our experience with the resolution of intra-abdominal abscesses in other locations had been so gratifying, we felt justified in continuing with conservative treatment, realizing that incision and drainage might become necessary should there be any exacerbation or any arrest in the healing process. The progressive increase in the pleural effusion did not alarm us, since we felt that this was only a supradiaphragmatic pleural reaction to infradiaphragmatic disease.

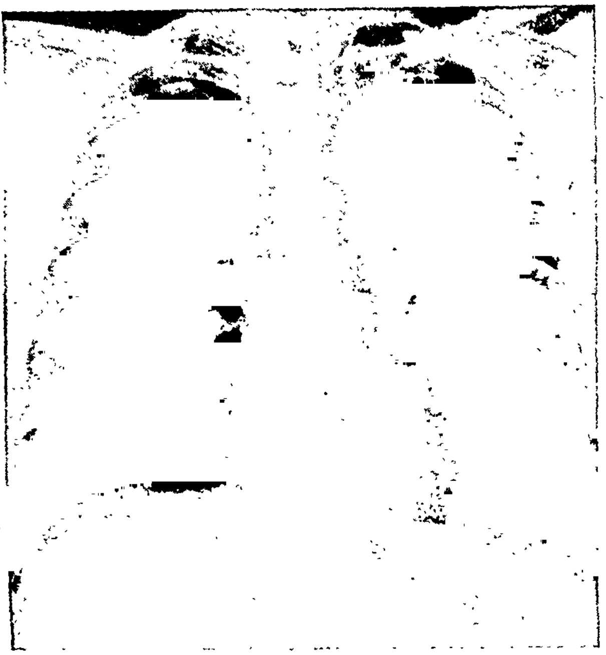

Fig. 3.—Chest roentgenogram, Nov. 1, showing normal lung fields, no effusion and a sharp outline of the right side of the diaphragm, which is no longer elevated.

Intravenous administration of oxytetracycline was continued for eight days in order to be certain that a high concentration of the drug would be maintained. Only after the leukocyte count had returned to a reasonably low level and after the patient was asymptomatic was oral therapy started. We felt oxytetracycline therapy should not be stopped until there was definite evidence of absorption of the subphrenic abscess. Thus this therapy was continued until there was evidence of decrease in the pleural effusion, indicating to us that the irritative phenomenon below the diaphragm was no longer active.

While the ideal method of selecting the proper drug would have been to have obtained a culture and then to test for the sensitivity of the offending organisms to various antibiotics, it was not felt safe to "needle" or drain the area in question at any time. Therefore a broad spectrum antibiotic was selected.

CONCLUSIONS

While we do not believe that the surgical principle of incision and drainage of abscesses is to be abandoned in favor of antibiotic therapy, we are in agreement with many others that we should reevaluate the management of abscesses, particularly in the so-called closed areas. Before the chemotherapeutic and antibiotic era, once an abscess had formed it was unusual for it to resolve, and the process was terminated by incision and drainage, spontaneous rupture with evacuation, or death.

Since Crile's report the conservative management of intra-abdominal abscesses with antibiotics has taken a definite place in our therapeutic armamentarium. As previously mentioned, one of us (J. Z.) has had excellent and sometimes surprising results employing antibiotics in the treatment of intra-abdominal abscesses. In the past five years he has not had occasion to incise and drain a pelvic abscess following ruptured appendicitis, all such abscesses resolving completely after continued intensive antibiotic therapy.

The management of intra-abdominal abscesses should be approached with an open mind. In all such cases conservative treatment should be given a fair trial, and, as in the case reported, should be continued only as long as there is obvious continued improvement in the patient's condition. Very often, the antibiotics will localize a spreading inflammatory process, and if the surgeon does not become impatient and institute incision and drainage at this point, continued therapy may cause complete resolution of the process. While it must be admitted that the nonoperative method of management may take longer than the operative in the eventual complete cure, the former method obviates an operative procedure with all the accompanying risks. Should the resolution of the process be arrested at any time, or should the general condition seem to be deteriorating with conservative therapy, surgical drainage can then be employed.

1930 Chestnut St. (Dr. Zaslow).

Therapeutic Radioisotopes.—The potential usefulness of radioisotopes can be illustrated through their substitution for x-rays. The cobalt^{60} isotope has a very hard gamma radiation. In this sense it is similar to radium. Since Co^{60} can be produced in large quantities and is cheaper than radium, it was quickly utilized as a radium substitute. Although there are many minor physical corrections to be considered, a cobalt needle will do everything a radium needle will do and will do it as well, but no better. However, since cobalt is plentiful and can be adapted to variable strength, shape, and sizes, extensions of the radium needle idea were easily visualized and have already been put into practice. Flexible threads of cobalt wire have been used. Powdered cobalt in plastic masses have been made. . . . The possibilities are limited only by the imagination of the investigator.—M. Brucer, M.D., Encouraging and Discouraging Research with Therapeutic Radioisotopes, *Journal of Kentucky State Medical Association,* June, 1953.

CONGENITAL ABSENCE OF A MAIN BRANCH OF THE PULMONARY ARTERY

Israel Steinberg, M.D.
Charles T. Dotter, M.D.
and
Daniel S. Lukas, M.D., New York

Ten cases of congenital absence of a main branch of the pulmonary artery have been reported in the literature.[1] The diagnosis was made at postmortem examination in seven instances [2] and during surgical exploration in two.[3] In only one recently reported case [1a] was the diagnosis made prior to surgery or death. In the two cases we are reporting, diagnosis was suspected on clinical and routine radiographic examinations and conclusively established by angiocardiography. Angiocardiography, pulmonary function studies, and cardiac catheterization were performed by methods previously described.[4]

REPORT OF CASES

CASE 1.—A 48-year-old practical nurse was first seen in the outpatient department five years ago. At that time, her chief complaint was of soreness in the chest and frequent sighing. A chest film taken a year earlier at another hospital was reported to have shown a mediastinal tumor. Bronchoscopy was not revealing, and no treatment was recommended.

Physical examination revealed the patient to be well developed, well nourished, and in no discomfort. Her weight was 63.7 kg.; height, 161.3 cm.; and blood pressure 150/80 mm. Hg. The only abnormality was hyper-resonance over the left side of the chest and diminution of the breath sounds over the right side. The thorax was symmetric, and respiration was equal bilaterally. Laboratory examinations including urine, blood, and blood chemistry studies and electrocardiography revealed nothing abnormal. The chest film (fig. 1 *A*) showed overdistention of the left lung with displacement of the trachea to the right. The right lung appeared small and showed marked diminution of the pulmonary vasculature. The heart was normal in size and shape, and there was no parenchymal disease of the lungs. Fluoroscopic examination showed an increased mediastinal shift toward the right on deep inspiration and a greater excursion of the left side of the diaphragm. Findings on bronchoscopy again were unremarkable. Angiocardiography (fig. 1*B*) revealed absence of the right pulmonary artery. Results of the pulmonary function studies are recorded in tables 1 and 2. The patient has been under observation for five years, and, during that period, there has been no dyspnea, although she continues to sigh and complain of vague discomfort in the chest. A low basal metabolic rate discovered in 1950 was corrected by treatment with thyroid.

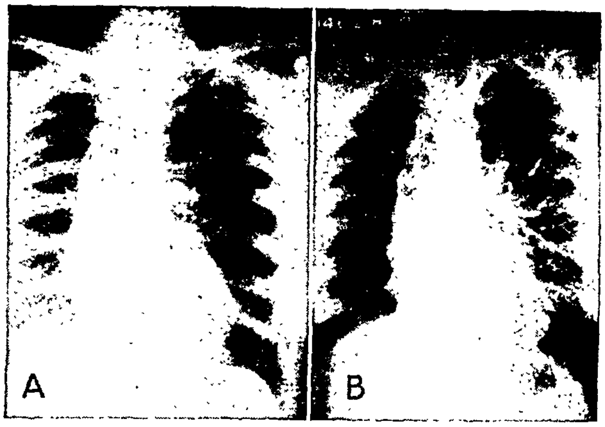

Fig. 1.—*A*, conventional frontal roentgenogram shows the left lung overdistended, causing tracheal deviation to the right and mediastinal herniation. Vasculature in small right lung is diminished. *B*, frontal angiocardiogram shows absence of right pulmonary artery. Left pulmonary artery and arterial tree are normal.

CASE 2.—A 24-year-old mechanic came to the hospital in January, 1952. Six years earlier, his enlistment in the Naval Reserve was terminated after a few weeks when it was seen on a routine chest film "that the right lung was pushed toward the heart." The patient was asymptomatic. Physical examination revealed him to be well developed and well nourished. His weight was 82 kg.; height, 183 cm.; and blood pressure, 142/72 mm. Hg. The chest was symmetric and normal except for hyper-resonance of the right lung and diminution of the breath sounds in the left lung. Routine laboratory studies and bronchography of both lungs showed nothing abnormal.

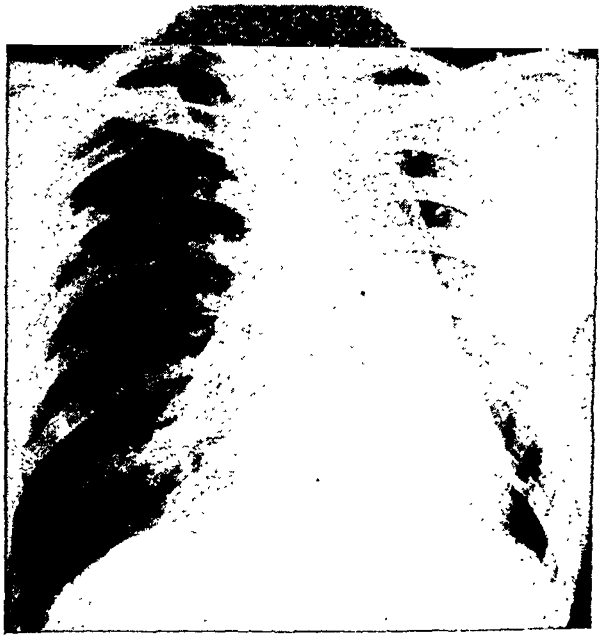

Fig. 2.—Conventional frontal roentgenogram shows marked overdistention of the right lung, left tracheal deviation, and mediastinal herniation. Left lung is small and has little vascularity.

Studies of pulmonary function are recorded in tables 1 and 2. Table 3 shows the data obtained by cardiac catheterization. A chest film (fig. 2) and fluoroscopy revealed that the right lung was overdistended and occupied two-thirds of the thoracic cavity. The trachea and mediastinum were shifted to the left. The lung fields were clear and well aerated; the heart was normal in size and shape. The diaphragm moved normally. Angiocardiography, both the frontal and left oblique views, demonstrated absence of the left pulmonary artery (fig. 3). The patient has remained asymptomatic.

COMMENT

Of the 12 reports of congenital absence of a main branch of the pulmonary artery now available in the literature, 10 of the patients were men and 2 were women. The right pulmonary artery was absent in eight instances, and the left was absent in four. The causes of death in the seven patients at autopsy were: hemorrhage into the lung not having a pulmonary artery,[1b] necrosis and tension pneumothorax of the unaffected lung,[1c] cardiac failure in two patients,[5] cyanotic congenital heart disease,[1f] and infection not related to the pulmonary artery in two.[6] Our patients and the one recently reported are the only ones free of serious cardiac and great vessel anomalies. The defects in embryologic development that produce absence of a branch pulmonary artery are poorly understood.[7]

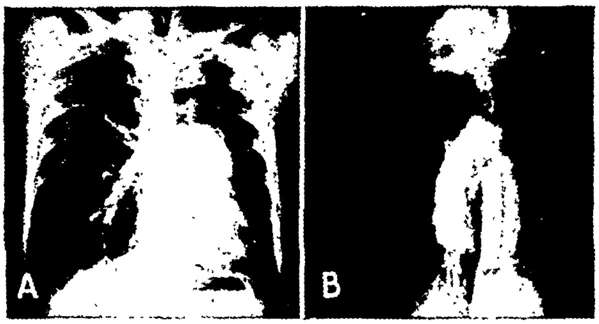

Fig. 3.—*A*, frontal angiocardiogram and, *B*, left oblique angiocardiogram show absence of the left pulmonary artery.

Absence of a main branch of the pulmonary artery produces characteristic changes in the appearance of the lungs on a conventional roentgenogram of the chest. One of the lungs is small and contains few vascular markings. The other lung is overdistended and well vascularized and displaces the mediastinal structures with the production of mediastinal herniation. Both lungs are clear, well aerated, and free of disease. The appearance of the mediastinal shift may arouse suspicion of a mediastinal tumor as it did in one of our cases. Angiocardiography is diagnostic in that absence of the branch of the pulmonary artery to the hypoplastic lung is evident (fig. 1*B* and 3). A systemic blood supply to the lung lacking pulmonary artery circulation was not demonstrated in our patients but probably exists, as it was present in 9 of the 10 patients previously reported.

Physiological studies confirmed the extremely mild functional disability present in our patients. Lung volumes, maximum breathing capacity, ventilation, and blood gases were normal in the man (case 2). The fact that the area of alveolar-capillary membrane available for gas exchange was sufficient is clearly demonstrated by the normal diffusion capacity for oxygen. If the area had been inadequate, the diffusion capacity would have been small.

In the older woman (case 1), increased residual and total lung volumes and slight diminution of maximum breathing capacity were definite evidence of fixed hyperinflation of the lungs, probably resulting from some loss of elasticity of the overdistended lung. Intrapulmonary mixing and alveolar distribution of air were normal, however, proving that true emphysema was not present. This patient was slightly dyspneic after the standard 30 step, one minute exercise.

Table 1.—*Lung Volumes and Ventilation Data (BTPS) of Two Patients with Absence of a Main Pulmonary Artery Branch*

	Case 1		Case 2	
	Observed	Predicted	Observed	Predicted
Lung volumes, cc.				
Vital capacity	2,820	2,761	4,601	4,582
Residual volume	1,803	844	1,082	1,145
Total capacity	4,623	3,608	5,883	5,727
$\frac{\text{Residual volume}}{\text{Total capacity}}$, %	39	23	18	20
Maximum breathing capacity, liter/min.	67	81	102	150
Ventilation, liter/min./sq. m. of body surface area				
Rest	3.8	3.2	3.6	3.6
Exercise	10.3	11.4	10.9	11
First min. recovery	....	....	12	12.5

The only significant defect in pulmonary function found in both patients was an increased dead space to tidal volume ratio resulting from ventilation of the lung not supplied by a pulmonary artery. The resting dead space, however, was not greatly increased; thus it was indicated that the vascular lung preferentially received the greater portion of each tidal volume. This was probably due to the smaller size of the avascular lung and further encroachment on it during inspiration by the herniated one.

Table 2.—*Blood Gases and Ventilation-Perfusion Relationships of Two Patients in Whom a Main Branch of the Pulmonary Artery Was Absent*

	Case 1	Case 2	Normal
Alveolar N_2 after 7 min. breathing oxygen, %	1.4	1.1	<2.5
Arterial blood			
Oxyhemoglobin saturation, %			
Rest	93.2	93.8	97
Exercise	..	94.3	97
pCO_2, mm. Hg	45	43	40
Alveolar-arterial oxygen gradient, mm. Hg	14	7	<12
$\frac{\text{Dead space}}{\text{Tidal volume}}$, %	34	34	<30
$\frac{\text{Venous admixture}}{\text{Pulmonary blood flow}}$, %	5	5	< 6
Diffusion capacity of alveolar membrane for oxygen, cc./min./mm. Hg	..	24	20

Since bronchospirometry was not done, it is impossible to calculate how much the lung without a pulmonary arterial blood supply contributed to gas exchange. Previous studies on man and animals indicate that such a lung is capable of exchanging gases to some extent by

---

5. Footnotes 1*d* and *e*.
6. Footnotes 1*g* and *h*.

virtue of blood flowing through bronchial artery-pulmonary capillary anastomoses.[8] Since the blood has been arterialized by passage through the normal lung, it is capable of releasing only subnormal amounts of carbon dioxide and combining with even slighter amounts of oxygen.

The normal pulmonary vascular bed is large enough to permit an increase in blood flow up to three times the normal resting value without increase in pulmonary artery pressure.[9] With greater flows, the pressure exceeds normal. On the basis of this knowledge of pulmonary circulation, it is not surprising that the resting pulmonary artery pressure in the man (case 2) was found to be normal, with a blood flow exactly twice the usual value through the normally functioning lung. Mild pulmonary arterial hypertension did develop during exercise that caused the cardiac output to be doubled. This change in output corresponds to a fourfold increase of pulmonary blood flow in a person with two normal lungs. In all respects, the pulmonary circulation in this patient (case 2) was like that in a person who has had pneumonectomy.[9b]

TABLE 3.—*Catheterization Data Obtained From Patient in Case 2*

	Rest		Exercise	
	Observed	Normal	Observed	Normal
Cardiac index, liter/min./sq. m. of body surface area	3.0	3.4	6.0	> 4.4
Pressures, mm. Hg				
Pulmonary "capillary" mean	8	<10	7	<12
Pulmonary artery				
Systolic/Diastolic	29/8	25/8	33/11	25/8
Mean	16	15	21	15
Pulmonary vascular resistance, dynes sec./cm.$^{-5}$	106	100	92	<100

The management of patients with this condition is relatively simple. Prompt treatment of any respiratory infection, particularly infection in the vascular lung, is essential. Since, if there is an increase in pulmonary blood flow, pulmonary arterial hypertension occurs more readily than normal, severe forms of exercise are contraindicated.

SUMMARY AND CONCLUSIONS

Two cases of isolated congenital absence of a main branch of the pulmonary artery are presented. The asymptomatic state of the patients is explained by the mild respiratory and cardiovascular disability observed on pulmonary function and cardiac catheterization studies. The ages of the patients, 53 and 26 years, and their continued well-being during follow-up examination suggests that the prognosis is favorable, barring any complicating disease of the "good" lung.

Such a diagnosis may be suspected when conventional roentgenogram of the chest reveals overdistention and mediastinal herniation of one lung with hypoplasia and diminished vascularity of the affected lung. Absence of a main pulmonary artery branch is conclusively demonstrated by angiocardiography. It is predicted that more instances of this entity will be recognized in this way.

DERMATOSES AMONG OFFICE WORKERS

George E. Morris, M.D., Boston

Skin eruptions among office workers are not common and thus have been seldom reported, but, inasmuch as they do comprise about 3% of the cases seen by the actively practicing industrial dermatologist, there has been a definite need of more literature on this subject. Prior to this writing, infrequent reference has been noted to unconnected cases of dermatitis from carbon paper and from contact with glue and typewriter ribbons. Schwartz, Tulipan, and Peck,[1] in pointing out that office workers may also suffer from erythema ab igne and dermatitis from the glue on stamps and envelopes, have urged that more attention be given to recording correlated cases of eruptions treated among office workers.

This is a report based on an analysis of 1,213 patients treated by me, all of whose dermatoses were proved to be caused by industrial factors. Among them were 36 office workers, who contacted the conditions as follows: 4 from carbon paper, 5 from paper, 6 from glue, 2 from cardboard, 12 from various machine dyes and inks and the chemicals used to remove them, 1 from paper towels, together with the 6 cases described in this report, which seem to be of especial interest.

REPORT OF CASES

CASE 1.—The patient, aged 45, was first seen in 1945. He complained of a rash of the finger webs and on his fingers, which he had endured for four years. He stated that he had never experienced any eruptions previous to the onset of the one on his hands, and he denied ever having had ringworm on his feet. He had been seen by four dermatologists, who had told him his rash was not due to his work. He said that he handled carbon paper and cards and that he cleaned his hands frequently with bar soap. On examination, all the finger webs were found to be red and vesicular, and the vesicles extended up onto the fingers. On two occasions, scrapings were taken for fungi, but the tests proved negative. The patient was told that his eruption could not be due to the nature of his work, and he was discharged from treatment. He was subsequently seen in 1951. He had then been attended by 11 dermatologists, including myself, and all 11 had found that his eruption was not due to his work. He stated that his hands had cleared up somewhat while he was on vacation in 1949, and had completely cleared in 1950 while he was in the hospital 10 weeks. His hands had started to break out again within a week after his return to work (fig. 1*B*). There was no change in the nature of his work as a clerk, and in the course of his daily duties he handled only paper, cards, and carbon paper. When questioned as to any other manifestations on his skin, he remarked that he had had a "burn" on his leg from foam rubber when his leg had been in traction while in the hospital. Questioning then brought out the fact that he used elastic rubber bands all day long in filing away his cards. On further inquiry, he then stated that he had had eruptions previously on his arm from elastic bands and on his leg from garters.

Thus, *11 years after the onset of his eruption, the patient* was patch-tested with elastic bands, with black carbon, and with red carbon, the result being that he showed a positive test to the elastic band and also the red carbon paper. He was told to avoid the use of carbon paper and elastic bands, and then he improved, only to break out subsequently with new blisters on his fingers, at which time he was found to have a positive patch test to a green rubber blotter on his desk. The blotter was removed, whereupon his skin cleared again, but

[1] Schwartz, L.; Tulipan, L., and Peck, S. M.: Occupational Diseases of the Skin, ed. 2, Philadelphia, Lea & Febiger, 1947.

broke out shortly after his office was furnished with green leatherette chairs. He was tested with a patch of the leatherette, and had a 3+ test to the green leatherette. The patient was removed from contact with all these materials and has been free of a dermatitis for over a year, while still working in the same office.

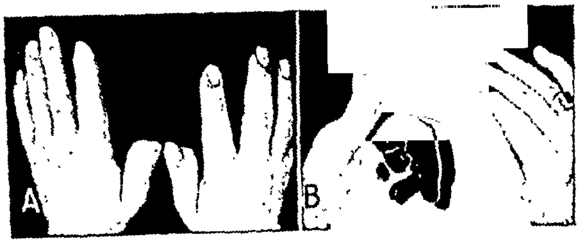

Fig. 1.—Dermatoses caused by contact with rubber products. *A*, caused by elastic rubber bands. *B*, caused by rubber thumb.

In addition to this case, three officer workers have been treated for eruptions emanating from their use of "rubber thumbs" or rubber finger-tops worn while counting or picking up cards in the course of their work (fig. 1*B*).

Case 2.—A clerical worker evidenced an eruption of her thumb and of the second and third fingers of her right hand, which had been present for over two months. She stated that she had been working in the same office during that period, and that she handled nothing but paper and pencils at her work. According to the patient, the eruption occurred in the places where she held the pencil while at work. She was wont to hold her pencil in an unorthodox manner, so that it touched the thumb and the approximating surfaces of the second and third fingers, as shown in figure 2*A*. She was patch-tested with the pencil, both as to the green outer paint and as to the wood on the inner part of the pencil. She had a negative test to the wood of the pencil, but a positive test to the green paint. She was removed from contact with colored pencils, and her eruption cleared.

Case 3.—A stenographer complained of an eruption (fig. 2*B*), which was found to be due to liquid soap from a soap dispenser in the office building where she worked. After elimination of other substances, it was noted that the rash occurred in the approximate places on the palms of her hands where the liquid soap had dropped after being released by means of the push-up plug. Test to the diluted soap showed a 4+ reaction. The eruption was cleared by the use of a cleanser (not a soap) with a pH of 7.

CONCLUSIONS

When a patient complains of a rash that he believes to be due to something encountered in his work, it is only prudent to test him with various materials with which he comes in daily contact. Dermatitis from rubber bands has not been emphasized as a cause of contact dermatitis. Failure to consider all the factors present was the reason why 11 dermatologists, including myself, missed the diagnosis in case 1. In that instance, certain vagaries were present, which could be disclosed only by patch-testing. Such vagaries were manifested by consistencies and inconsistencies, i. e., the patient had a positive test to elastic, which is one form of rubber, to a green rubber blotter, to a green leatherette chair (which may have been made partially from rubber), and also to a red carbon paper, whereas tests to blue carbon and to a black leatherette book cover proved negative.

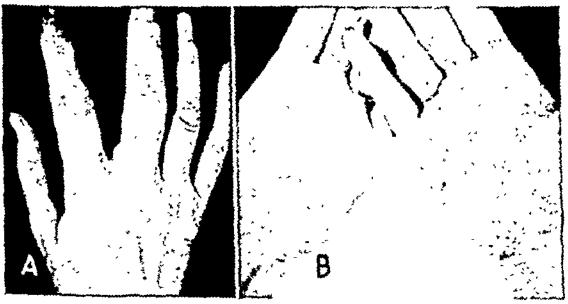

Fig. 2.—Dermatoses caused by contact with common equipment. *A*, caused by paint from pencil. *B*, caused by liquid soap.

VOLVULUS OF THE SMALL INTESTINE COMPLICATING PREGNANCY

REPORT OF A CASE

Phillip H. Halperin, M.D.,
Bela Kent, M.D.,
and
Sidney Rubin, M.D., Kansas City, Mo.

This case of intestinal obstruction is reported because it not only is a rare complication of pregnancy but also is a diagnosis seldom considered since the symptoms so closely simulate those occurring in normal pregnancy. Only six cases have been reported in the American literature.

The patient was a 19-year-old pregnant woman whose last menstrual period was in August, 1951. Two years prior to her pregnancy she had had an appendectomy with an uneventful postoperative period. The patient suffered rather severe hyperemesis gravidarum and displayed a marked anxiety state during the first three months of pregnancy. With frequent reassurance, her fear of pregnancy and childbirth disappeared, and the hyperemesis lessened, although it never stopped completely. She first felt life in November. On Dec. 16, 1951, at 4 a. m., the patient awoke with severe upper abdominal pain and vomiting. The acute pain and vomiting subsided for several hours, and upon recurrence of these symptoms she was admitted to the hospital. On admission she did not appear to be acutely ill. Her temperature was 98.6 F, pulse rate 90, and blood pressure 120/80 mm. Hg. The fundus of the uterus was soft and was palpable one fingerbreadth above the umbilicus; no contractions were observed. The fetal heart rate was 150 and regular. The upper abdomen was not distended, and no rigidity was evident. There was no increased peristalsis and no palpable tumor mass. Meperidine (Demerol) hydrochloride (100 mg.) was given to relieve pain, and 1,000 cc. of 5% glucose in saline, and 1,000 cc. of 5% glucose in water with Lyo-B-C (a preparation containing the principal B complex factors and ascorbic acid) was given intravenously to prevent dehydration. The condition was first believed to be pyelitis of the left kidney, since the pain was more pronounced in the left flank. The total leukocyte count was 12,500. A differential count showed 85% polymorphonuclears and 12% stab cells. After a urine specimen was obtained by catheterization, 600,000 units of penicillin and 1 gm. of streptomycin were given. Results of urinalysis were negative. The patient spent a fairly comfortable day. The tenderness in the upper abdomen shifted to the right upper quadrant, and the vomiting still persisted; however, no rigidity or masses were found. The pulse and temperature remained within normal limits. The possibility of intestinal obstruction was considered, and a flat roentgenogram of the abdomen was

---

From the Department of Surgery, Menorah Hospital Medical Center, and University of Kansas Medical Center (Dr. Halperin), the Department of Obstetrics and Gynecology (Dr. Kent), and the Department of Radiology (Dr. Rubin) Menorah Hospital Medical Center.

taken (fig. 1). This scout film revealed no undue distention of the small bowel, and gas was seen distributed throughout the large intestine; thus, there were no signs of obstruction. The patient still needed an occasional dose of meperidine for relief of the pain, but the vomiting had subsided. A laxative was given at bedtime, and the next morning, on the third hospital day, an enema was given with fair results. The patient felt comfortable, retained all of her food, and complained very little of pain. At this time masses still were not evident although there was some distention and localized tenderness in the right upper abdomen. The possibility of cholecystitis and cholelithiasis was considered, but the tenderness was lower than the gallbladder region. On the fourth hospital day the patient was almost completely free of subjective symptoms. She had several small bowel movements and felt well. Examination at this time revealed a soft, tender mass in the right upper abdomen with very little distention. The temperature was 99.6 F and the pulse rate 100.

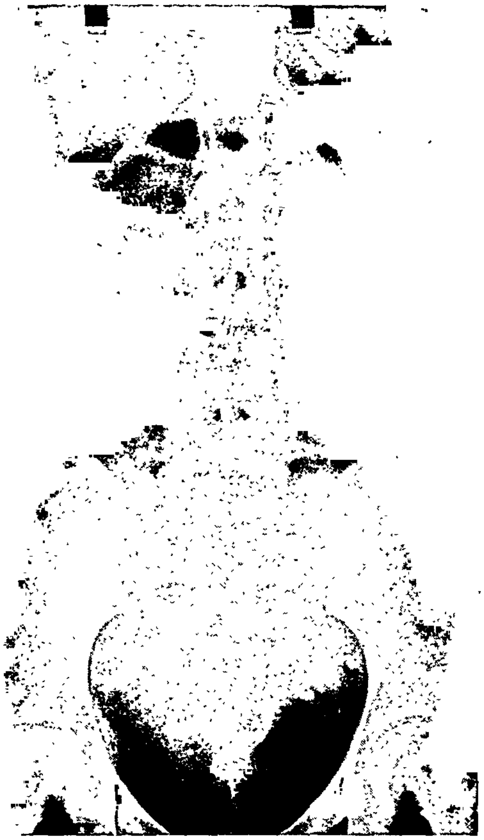

Fig. 1.—Roentgenogram revealing gas scattered throughout the large intestine. Some bowel gas is visualized in the upper right quadrant. A soft tissue mass extends upward from the pelvis to the level of the fourth lumbar body. A fetus of five months' gestation is present within the uterus.

On the fifth hospital day the patient started to vomit again. The pain increased, and the mass was larger and tender. The leukocyte count increased to 24,000, with 57% polymorphonuclears, 28% stab cells, and 10% lymphocytes. Clinically the diagnosis of intestinal obstruction was obvious, and a second scout film (fig. 2) revealed distention similar to that seen in small bowel obstruction. In addition there was a loss of the valvulae conniventes, which we believed to be suggestive of vascular impairment. The patient was prepared by adequate fluids and intestinal decompression, and, the same day, exploratory operation was performed through a right upper rectus incision.

When the abdominal cavity was opened, the omentum was found encasing the mass. The omentum was carefully dissected away, revealing two loops of jejunum that were dilated to approximately 8 cm. The loops were almost black and were lusterless, with definite loss of normal motility. The loops of small intestine were carefully dissected from the surrounding structures. A torsion at the base of the mesentery was found. This was uncoiled, and then a resection 5 cm. proximal and distal to the area of infarction was accomplished. An end-to-end anastomosis was performed, an outer row of 4-0, gastrointestinal silk sutures placed at intervals of 4 to 5 mm., and interrupted 4-0, gastrointestinal absorbable surgical sutures used for the inner row. A peritoneal graft was then cut from the wound edge and used as a patch over the anastomotic line as described by Chester, Bell, and McCorkle.[1]

The patient was treated by intestinal decompression with the Miller-Abbott tube while receiving fluids intravenously for five days. After this she was given soft foods. She made an uneventful recovery and was discharged on the 11th postoperative day. At no time during the illness was her pregnancy threatened. On May 5, 1952, the patient delivered a full-term, viable boy. There were no complications during the delivery, and the patient has gained 20 lb. (9.1 kg.) since surgery was performed.

COMMENT

In evaluation of this case, the difficulty in making a correct diagnosis is readily evident. In normal pregnancy pain may be associated with vomiting, distention, and constipation, all prevalent classical signs and symptoms. Upper abdominal pain is not uncommon during pregnancy, because the diseases of the upper abdominal organs are relatively common during this period. Thus, gallbladder disease, kidney infections, hyperacidity of the

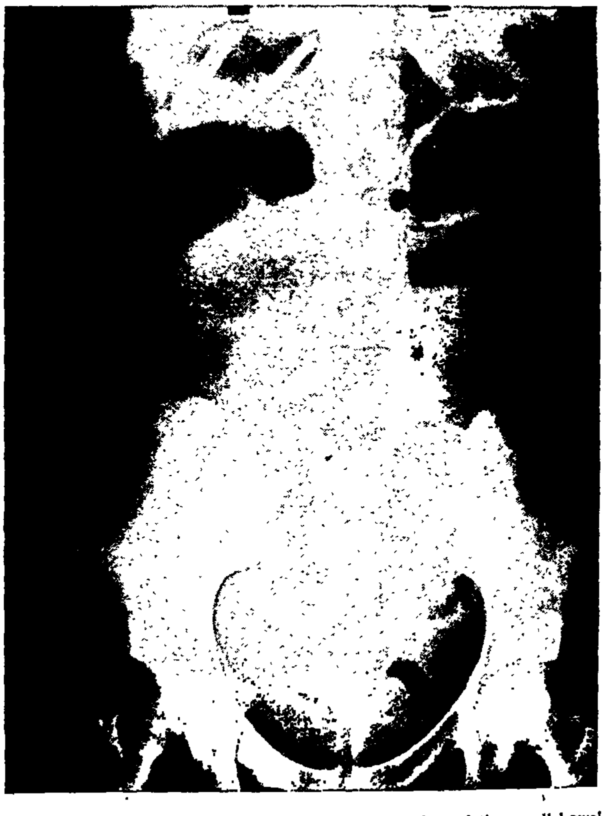

Fig. 2.—Follow-up film demonstrating the distention of the small bowel with an abrupt loss of valvulae conniventes in suspected jejunal loops. Note that air is still observed in the large intestine, a finding not infrequent in volvulus of the small intestine.

stomach, premature labor, separation of the placenta, and degeneration of fibroids will initiate the same kind of symptoms as intestinal obstruction.

Vomiting is one of the commonest symptoms of normal pregnancy. Although most textbooks state that the typical hyperemesis gravidarum does not last longer than three months, every obstetrician has had patients who have vomited all through pregnancy. The same difficulties are encountered if we look for the physical signs of intestinal obstruction. Distention can be caused by other conditions such as the ileus associated with pyelitis.[2] If the obstruction is high, distention may not be marked. Visible peristalsis may sometimes be observed in the lower intestinal tract during the first trimester of normal pregnancy.

Pregnancy per se may cause intestinal obstruction under exceptional circumstances such as those described by Dibot. In his case, the uterus contained 14 liters of amniotic fluid in addition to twin fetuses. The marked enlargement of the uterus caused mechanical pressure on the rectosigmoid. Torsion of the small intestine has been caused by mesenteric cysts, acute appendicitis, Meckel's diverticulum, and inflammatory adhesions. The commonest location for volvulus has been in the sigmoid, where torsion was the cause in 41 of the 80 reported cases. In 19 of the remaining 39 cases, other portions of of the large intestine were involved. Thus, in only 20 cases was the volvulus confined to the small intestine, as in this case.[3]

The roentgenologic diagnosis of acute intestinal obstruction is some times very difficult. The confusion is due to the occasional true ileus of pregnancy that is observed in normal pregnancy or associated with a pyelitis.[2] In each case, the radiological report must be integrated with information gathered from the history and physical examination. In cases in which the clinical findings suggest an obstruction, a follow-up scout film should be made within 12 to 24 hours. This procedure should be emphasized, because it demonstrates the progression of gaseous distention that is so important in diagnosis of obstruction. The serial film confirmed the diagnosis in this case and has been valuable on other occasions when the original film was inconclusive. Furthermore, the serial flat plate suggested impairment of blood supply in that the appearance of the jejunal loops showed an abrupt loss of valvulae conniventes.

The treatment of volvulus is surgical intervention as soon as the diagnosis is made, except when the patient has reached the third trimester of pregnancy and the size of the uterus interferes with the surgical procedure. Because of the height and size of the uterus at this stage it may mechanically displace the intestinal loops so that they become inaccessible. In such circumstances it is advisable to induce labor, empty the uterus, and then proceed with the laparotomy. Some physicians feel that the emptying of the uterus may release the obstruction, or volvulus, but we believe that this is a dangerous procedure in that valuable time is wasted in observation of the patient after delivery. The prognosis is improved when the patient is operated on at the earliest sign of obstruction. When there has been undue delay in surgical intervention the maternal mortality approaches 60%.

SUMMARY

Early diagnosis of volvulus of the small intestine occurring during pregnancy is difficult, because some of the normal signs of pregnancy are similar to signs observed in cases of obstruction. The importance of employing not only a single scout film of the abdomen but also a follow-up film in 12 to 24 hours is emphasized. In early volvulus the first roentgenogram may disclose no abnormality and thus be misleading. Diagnosis of obstruction of roentgenogram is further complicated by the fact that normal ileus of pregnancy must be differentiated from obstruction. The prognosis is greatly improved if the volvulus is diagnosed early and surgical correction undertaken. Delay is responsible for almost a 60% maternal mortality.

HEMOPERICARDIUM WITH TAMPONADE DURING ANTICOAGULANT THERAPY OF MYOCARDIAL INFARCT

REPORT OF A CASE WITH RECOVERY FOLLOWING PERICARDIOTOMY

O. Alan Rose, M.D.
Roy H. Ott Jr., M.D.
and
Herbert C. Maier, M.D., New York

Significant pericardial hemorrhage has been reported to have resulted from a number of precipitating factors during the administration of anticoagulants. These include nonpenetrating trauma to the heart,[1] tumor involving the pericardium, and pericarditis of the nonspecific type [2] as well as that associated with myocardial infarction. Reports of hemopericardium with tamponade complicating anticoagulant therapy of acute myocardial infarction have been made by Nichol [3] and by Goldstein and Wolff.[4] Syner [5] has reported a case with relief of tamponade by pericardial aspiration. The purpose of this paper is to report a case in which the relief of cardiac tamponade by pericardiotomy was a life-saving measure.

REPORT OF A CASE

A 48-year-old accountant was admitted to Lenox Hill Hospital on March 4, 1952, with the complaint of a burning sensation in the throat and substernal region. This had been noted for the previous two days on walking and had been constant for the four hours prior to admission. There was accompanying weakness, nausea, and diaphoresis. The past history was un-

remarkable. There was no evidence of previous coronary insufficiency, hypertension, or diabetes. The patient's father died of heart disease at the age of 53. The review of systems was negative.

The physical examination revealed a well-developed, well-nourished white man, in no apparent distress. The temperature was 98.4 F (R), pulse 60, respirations 19, and the blood pressure 140/90 mm. Hg. The heart was not enlarged and had sounds of good quality. No murmur, rub, or gallop was heard. The rhythm was regular, with the ventricular and peripheral rates equal. There were no signs of congestive heart failure.

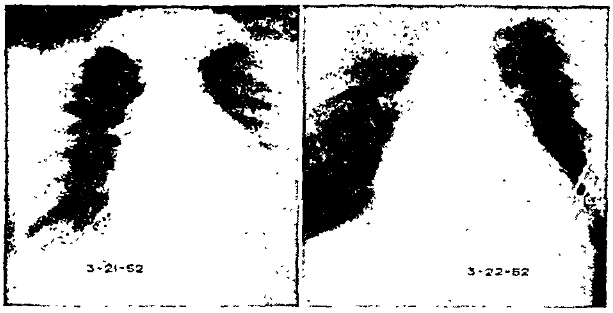

Fig. 1.—Bedside films of patient with cardiac tamponade after anticoagulant therapy taken the day prior to and immediately following surgery.

The electrocardiogram on admission showed marked depression of the ST segments in lead 1, elevation in leads 2 and 3, and depressed ST segments in the precordial leads, where inverted T waves were present. Except for variations, which will be noted, subsequent cardiograms showed the progressive changes seen in posterolateral myocardial infarction. The white blood cell count was 11,600 and the erythrocyte sedimentation rate 37 mm. per hour (Westergren).

The patient was placed on a coronary regimen with bed rest, oxygen, sedation, narcotics as needed, and anticoagulants. Heparin was given subcutaneously in a dose of 50 mg. every 6 hours for 48 hours. Bishydroxycoumarin (Dicumarol) was administered, 300 mg. initially, then 200 mg. and 150 mg. on consecutive days. On the second hospital day, the temperature rose to 102 F (rectal), but he had no complaints. On the third day, he complained of almost continual aching substernal pain. A pleuropericardial friction rub was heard. The prothrombin time was 25 seconds (control, 11 to 13 seconds). The patient still had a temperature of 101 to 101.8 F (rectal), and chest pain persisted. A slight friction rub was heard inconstantly. There were no signs of congestive heart failure, and the patient seemed to be improving.

On the eighth hospital day, a more marked friction rub was heard over the entire precordium. It was closer to the ear, louder, and more leathery in quality than the previous rub. The electrocardiogram showed ventricular premature systoles and short runs of ventricular tachycardia. These were controlled by oral administration of procaine amide hydrochloride (Pronestyl). The prothrombin time was 39 seconds (control, 11-13 seconds). The patient's temperature slowly dropped, and he appeared improved. The heart sounds were of better quality and the intensity of the friction rub lessened. On the 12th hospital day, the patient began to complain of nausea, which was followed by vomiting. His skin became pallid and cold. The prothrombin time was 41 seconds (control, 11 to 13 seconds). On the 13th day, his venous pressure was 250 mm. H_2O. He was digitalized and given mercurials with little or no response.

On the 14th day, his chest was clear and the heart sounds were of poor quality and intensity. There was evidence of cardiac enlargement. The blood pressure was paradoxical, being unobtainable during the inspiratory phase of respiration but during expiration, pressures of about 100/70 mm. Hg were present. The liver was palpable 4 fingerbreadths below the right costal margin. No peripheral edema was noted. An electrolyte imbalance was found with a serum sodium of 126 mEq. per liter and a potassium of 6.3 mEq. per liter. The blood urea nitrogen rose from normal levels to 76.4 mg. per 100 cc. During the next four days, the serum sodium ranged from 118 to 120 mEq. per liter, and the serum potassium from 6.4 to 5.9 mEq. per liter, with a hematocrit of 42.9 to 38.2%. The plasma chlorides ranged from 543 to 506 mg. per 100 cc. (570 to 620 mg. per 100 cc., normal). The venous pressure was 300 mm. H_2O. The prothrombin time rose abruptly on the 14th day to 84 seconds, (control, 11-13 seconds), and anticoagulants were discontinued. Synthetic vitamin K was given intravenously. The prothrombin time returned to the previous levels and then to normal. Roentgenograms showed increasing heart size. The form of the electrocardiogram did not change, but the voltage became progressively lower. It was still not possible to differentiate with reasonable certainty between cardiac dilatation and pericardial effusion with tamponade. The cardiac status continued to deteriorate.

On March 21, 1952, the 18th hospital day, physical signs and x-ray evidence (fig. 1) were considered to be more consistent with cardiac tamponade than with dilatation. The following day, the prognosis with no further treatment appeared hopeless and a pericardiotomy was performed with the patient under local anesthesia. About 700 cc. of hemorrhagic fluid was removed. It contained 5.8 gm. of hemoglobin per 100 cc. and did not clot. During controlled release of pericardial fluid, the pulse pressure progressively increased. The blood pressure changed from 90/70 mm. Hg, obtainable only during the expiratory phase of respiration, to 130/80 mm. Hg, throughout the respiratory cycle. The patient's condition improved rapidly. Serosanguineous pericardial fluid continued to drain for several days. During the subsequent 24 hours, the urinary output exceeded 5 liters and was of extremely low specific gravity. For the following three days, his urine output was between 3 and 4 liters per day, and the total fluid output exceeded the intake with a negative fluid balance of 2 to 3 liters for five days. The electrolyte balance and blood urea nitrogen returned rapidly to normal. The venous pressure on the 24th day was 98 mm. H_2O.

On the 24th hospital day, generalized lesions of erythema multiforme developed, which were considered to be due to penicillin given postoperatively. In the eighth week of his illness, the patient began ambulation, which was interrupted by a febrile illness with temperature to 103 to 104 F (rectal), tachycardia, and generalized muscular aches and pains, probably viral in nature. He stood this complication well, without any symptoms of coronary or cardiac insufficiency. Ambulation was continued, and the patient was discharged asymptomatic. The heart showed only slight generalized enlargement and the sounds were of good quality. The blood pressure was 120/80 mm. Hg. The electrocardiogram showed the residual pattern of posterior myocardial infarction. Discharge was on the 71st hospital day. The patient has had an uneventful convalescence and has returned to his previous employment. Follow-up examinations to eight months since infarction have revealed no evidence of diminished reserve. The heart size has returned to normal by x-ray examination (fig. 2).

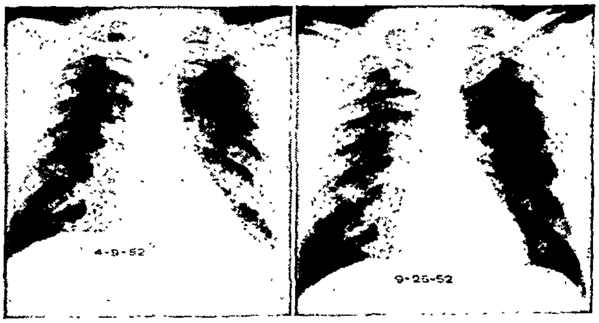

Fig. 2.—Six foot films showing the heart size 18 days and 6 months postoperatively.

COMMENT

Pericardial hemorrhage with tamponade in this case was undoubtedly related to the effects of anticoagulants. Although the prothrombin time later became considerably prolonged, hemopericardium occurred when the prothrombin levels were within the so-called therapeutic range and there was no evidence of toxic reaction to bishydroxycoumarin. Hemorrhage under these circumstances must be presumed to be a response that may occur when the normal clotting mechanism is disturbed in the presence of an inflammatory process. Hemopericardium with tamponade, which was considered to be due to the administration of anticoagulants, has been described in a case of nonspecific pericarditis.[2] This demonstrates that pericardial hemorrhage may result when anticoagulants are used in the presence of pericarditis of any type. While there is some difference of opinion,[6] most of the evidence in the literature agrees with our experience: serious complications of anticoagulant therapy are unusual when the necessary precautions are observed, and significant pericardial hemorrhage is relatively rare. Experimentally, surface hemorrhages were found to be no commoner in anticoagulant-treated myocardial infarction than in controls.[7] For these reasons, we do not believe that the possibility of this or other hemorrhagic complications should militate against the use, but should be regarded as a calculated risk in the anticoagulant treatment of myocardial infarction. A recent editorial has also expressed this viewpoint.[8]

Careful observation for manifestations of bleeding is, of course, essential and will usually prevent the occurrence of serious hemorrhagic complications. The earliest indication of pericardial hemorrhage, as pointed out by Goldstein and Wolff[4] and demonstrated in the case reported here, may be the occurrence of a pericardial friction rub when the prothrombin time is in the effective therapeutic range. This, with or without subsequent evidence of tamponade, warrants discontinuation of anticoagulants and the use of antihemorrhagic therapy. Tamponade may escape early recognition. It is evidenced by a rising venous pressure accompanying an increase in heart size, a small thready pulse, and narrowed pulse pressure, characteristically with a paradoxical quality to pulse and blood pressures. The heart sounds are not necessarily distant.

Differential diagnosis between cardiac dilatation with failure and cardiac tamponade may be difficult. Failure following myocardial infarction is most often predominantly left-sided as opposed to the almost exclusively right-sided effects of mechanical obstruction in acute tamponade. The electrocardiogram may be helpful in this differentiation when there is rapid development of low voltage complexes; however, the electrocardiogram as well as the x-ray findings may be equivocal.

Evidence of increasing tamponade is the indication for pericardial tapping. We believe that pericardiotomy, as performed in this case, is preferable to pericardiocentesis if differentiation from cardiac dilatation is uncertain because it permits direct visualization. The procedure can be performed under local anesthesia with the patient well sedated, receiving continuous oxygen. There is surprisingly little trauma when pericardiotomy is done by an experienced thoracic surgeon.

Of additional interest was the transient marked hyponatremia and chloremia and the hyperpotassemia. This appears to have been entirely due to the cardiac tamponade as there was a rapid and progressive return to normal electrolyte levels following pericardiotomy.

SUMMARY

A case is presented with pericardial hemorrhage and tamponade as a complication of anticoagulant therapy for acute myocardial infarction. Pericardiotomy was a lifesaving procedure.

APLASTIC ANEMIA FOLLOWING CORTICOTROPIN THERAPY

George G. Snively, M.D.
Paul G. Hattersley, M.D.
and
Lewis E. Nolan, M.D., Sacramento, Calif.

Allergic reactions to corticotropin have been documented recently with increasing frequency. These reactions have been of varying degree and, although most reported reactions have been of relatively benign nature, instances of nearly fatal anaphylactic shock have been described by Segal[1] and Feinberg and associates.[2] Several series of less severe reactions have also been reported.[3] The incidence of sensitivity reactions to this material has been variously reported up to as high as 5%.[3b]

Since corticotropin has been clearly shown to act as an allergen, one might anticipate bone marrow depression to be a resultant phenomenon in a certain number of those persons who manifest hypersensitivity to the drug. This we believe to have occurred in the following case and feel that it should be reported in view of the obvious importance of early recognition of such a reaction.

REPORT OF CASE

A 21-year-old white man was admitted on Oct. 21, 1952, complaining of chronic diarrhea. Diarrhea had persisted for about three years; there were 5 to 10 stools daily, with occasional blood and mucus. There was moderate anorexia and marked weight loss. Two previous hospitalizations resulted in only transient, symptomatic improvement. The medical history was not significant except for a 17 day hospitalization at the age of 7 years for bloody diarrhea. There were no allergies or

known food or drug sensitivities. On physical examination, this young man appeared sallow and listless. There were evidences of chronic weight loss. His blood pressure was 125/80 mm. Hg; his temperature, pulse, and respirations were normal. The entire physical examination was unremarkable except for the rectal examination, during which a roughened, nodular mucosa was felt. It was studded with elevated areas 1 to 10 mm. in diameter. Proctoscopic examination disclosed pseudopolyp formation on an ulcerated background of inflamed mucosa. Laboratory studies showed a normal urine; hemoglobin level, 9.5 gm. per 100 cc.; and white blood cell count, 4,800 per cubic millimeter. Several stools gave positive benzidine and guaiac reactions. Roentgen studies included a normal chest film and a roentgenogram after a barium enema that was reported to show loss of the haustral markings, with an unnaturally smooth appearance. There was shortening of the entire colon, with pseudopolyp formation throughout, and the terminal ileum seemed dilated but had a normal mucosal pattern. The appearance, to the radiologist, was characteristic of chronic ulcerative colitis, somewhat more advanced than on films taken two years previously.

In view of the long duration of the disease and the far advanced changes manifest in the colon, the patient was considered probably to be beyond adequate medical therapy, and a preparatory regimen for total colectomy was begun. Corticotropin was given by intravenous drip, 15 mg. daily, beginning on Nov. 21, 1952. His clinical progress was not satisfactory; he failed to gain weight, and the expected side-effects of the corticotropin did not develop. The administration of corticotropin was discontinued, and corticotropin gel was given in a dosage of 50 mg. twice daily, beginning on Nov. 26, 1952. Both the aqueous and gel forms of the drug were prepared from pork adrenal.[4] Two units of whole blood were given and administration of potassium chloride was begun on Dec. 5, 1952. Acne and a slight dependent edema developed on Dec. 7. Administration of carbacrylamine resins (Carbo-Resin), a sodium removing resin, was begun on Dec. 9, 1952, in an attempt to limit the retention of sodium. On Dec. 17, popliteal thrombophlebitis developed in the right leg; this was treated conservatively. At this time the hemoglobin level was 12.8 gm. per 100 cc.; hematocrit, 44%; and white blood cell count, 2,500 per cubic millimeter, with 79% neutrophils and 21% lymphocytes. Shortly thereafter marked generalized tenderness of all the muscles developed, and the temperature rose to 103 F. An electrocardiogram at this time showed a marked change from a previously normal tracing, with the development of a severe tachycardia and S-T segment depressions throughout all leads. On Dec. 23, the hemoglobin level was 14.5 gm.; white blood cell count, 1,300, with 75% neutrophils and 25% lymphocytes. On the following day, the hemoglobin level was 13.2 gm.; white blood cell count, 800, with 18% neutrophils and 82% lymphocytes. At this time, a sternal bone marrow aspiration was performed. The material showed almost no hematopoietic activity. The predominant cells were lymphocytes, and there were large areas of fat that were completely acellular. Many of the cells appeared to be degenerating granulocytes; the nuclei of some of these cells were pyknotic, while others showed nuclear lysis. Many showed cytoplasmic vacuolization. There were no normal granulopoietic or erythropoietic elements, and no megakaryocytes were found.

Corticotropin therapy was stopped and cortisone and antibiotic therapy begun. Oliguria developed; a fever continued; and the patient became disoriented. Rectal incontinence and bloody diarrhea developed. The administration of cortisone was discontinued after disorientation developed. On Dec. 25, 1952, 500 cc. of fresh blood was given, but the patient's condition rapidly grew worse and he died on Dec. 26. A review of the medications given to the patient prior to the sudden change in his clinical course disclosed that he had received only ferrous sulfate, a multivitamin preparation, potassium chloride, and the nonabsorbable carbacrylamine resins in addition to corticotropin.

An autopsy was begun approximately 45 minutes after death. On opening the abdominal cavity, the peritoneal surfaces were seen to be injected and reddened, and loops of bowel were slightly adherent, with a fibrinous exudate; no free fluid was found. The pleural spaces were normal. The pericardium and epicardium contained occasional, minute hemorrhagic areas. Numerous small, rubbery, dark red infarcts were found in both lungs, and a major branch of the right pulmonary artery was blocked by a red, mixed thrombus. The adrenals contained a markedly hypertrophied cortex 6 cm. thick; the medullas were normal in appearance. The serosa of the small bowel was injected and somewhat rough; the mucosa was normal; and the lumen was empty. The wall of the entire colon was markedly thickened and showed complete loss of haustration, extensive ulceration of the lining epithelium, and the formation of islands of pseudopolyps that were separated by dark red necrotic tissue. The vermiform appendix showed changes identical to those in the colon. The kidneys weighed 160 gm. each, and small necrotic abscess areas studded both the cortices and medullas on section. Examination of both sternal and rib marrow cavities showed a red, very dry surface from which no marrow could be expressed. The right leg was swollen, and there was induration over the course of the saphenous vein. There was a small area of ecchymosis, with induration in the left palm measuring 5 mm. in diameter. This region was incised and cultures made that disclosed a pure growth of beta hemolytic Staphylococcus aureus.

Microscopic findings included necrosis of the entire mucosa of the colon except for minute islands of epithelium and an exudative infiltration of all layers of the wall by polymorphs and lymphocytes. There was marked hypertrophy of the zona reticularis of the adrenal cortex. Areas of infarction and thrombosed blood vessels were found in the lung sections; chronic suppurative lymphadenitis was noted in the mesenteric lymph nodes; there was some infiltration of the pericardium by an inflammatory cellular exudate; and there were several minute areas of hemorrhage in the heart muscle. The kidneys showed microscopic evidence of the abscess areas noted grossly, and several similar areas were seen in the liver. Bone marrow sections showed diminution of the cellular components, most of which were lymphocytes with occasional plasma cells. No evidence of erythropoietic or myelopoietic activity was seen.

The pathological diagnoses were chronic ulcerative colitis; aplastic anemia; acute fibrinous peritonitis; pulmonary embolism, with bilateral pulmonary infarction; and pyemia, involving subcutaneous tissue, kidneys, liver, and pericardium.

SUMMARY AND CONCLUSIONS

A case of depression of bone marrow activity following corticotropin therapy with fatal termination due to overwhelming sepsis is presented. It represents, to our knowledge, the first instance of what we believe to be a probable untoward reaction to corticotropin. The experience points out a new potential hazard to be considered in the use of an ever more commonly administered therapeutic agent and demonstrates the need for careful hematological observation in patients so treated. As Evans and Rackemann [5] have commented, it is paradoxical that a drug that usually relieves allergic manifestations can itself act as an allergen; a somewhat similar situation, however, has been seen in the clinical use of antihistamines. Certainly the animal protein nature of corticotropin would make understandable such a potential for hypersensitivity development.

CLINICAL EXPERIENCE WITH TRANSFUSIONS OF PLATELETS SEPARATED FROM NORMAL BLOOD

Allen H. Minor, M.D.
and
Lee Burnett, M.S., New York

The development of a method for separating and concentrating platelets from normal blood[1] has facilitated the use of platelet transfusions for prevention or control of bleeding in thrombocytopenic purpura. Fifty-seven platelet concentrates, most of which were processed from five pints of blood each, have been prepared in the Lenox Hill Hospital's Laboratory for Experimental Cytology and given to 28 patients with thrombocytopenic purpura. To obtain an objective clinical evaluation of these transfusions, the observations and impressions of the 24 physicians attending these patients have been reviewed. This report is a summary of their experience.

CLINICAL MATERIAL

The 28 patients studied were divided, according to prognosis, into two groups of 14 each. Group A consisted of patients who might be expected to have a good prognosis, provided the hemorrhagic diathesis could be temporarily controlled. Ten patients in group A had idiopathic thrombocytopenic purpura, and four had thrombocytopenia secondary to severe but transient depression of the bone marrow, in which the number of megakaryocytes was usually normal or increased. Bone marrow depression in the latter four patients was caused by lipid histiocytosis of the kerasin type (Gaucher's disease) in one, septicemia in one, sulfisoxazole[2] in one, and triethylene melamine in one. Group B comprised patients in whom the ultimate prognosis was poor. Nine had aplastic anemia, three had acute leukemia, one had chronic granulocytic leukemia, and one had metastatic cancinoma involving the bone marrow; in these patients, the megakaryocytes were usually decreased in number or almost absent. The ages of the patients ranged from 2 to 69 years and were fairly evenly distributed throughout the seven decades.

Clinical evidence of bleeding was present in each patient at the time of the first platelet transfusion, despite attempts at control in many instances. Bleeding tended to be less severe in and therapy was less often given to patients of group A than to those of group B, as shown in the following tabulation:

Degree of bleeding	Group A	Group B
Slight	2	0
Moderate	6	4
Severe	6	10
Therapy		
Corticotropin or cortisone	3	4
Fresh blood	1	2
Corticotropin or cortisone plus fresh blood	5	8
None of the above	5	0

RESULTS

Effect on Hemostasis.—Platelet transfusions were given to prevent or control bleeding in 10 patients in group A and 13 patients in group B and to assist hemostasis at surgery in 4 patients in group A and 1 patient in group B. The desired effect was achieved either partially or completely in most patients in both groups, as shown in the following tabulation:

	Group A	Group B
Complete hemostasis	9	6
Partial hemostasis	3	4
No hemostasis	2	4

Thus, there were 17 patients who were not surgically treated and in whom a hemostatic effect occurred; the duration of this effect, as shown in the following tabulation, was usually greater in group A than in group B patients:

	Group A	Group B
Less than 1 day	0	3
1 or 2 days	3	4
3 or 4 days	1	1
More than 4 days	4	1

More than one platelet transfusion was given to 14 of the 28 patients. Transfusions were repeated less often in group A patients than in group B patients, and the time interval between transfusions tended to be greater in group A patients, as the following tabulation shows:

Number of transfusions	Group A	Group B
Two	3	5
Three	1	0
Four	1	1
Five	0	2
Six	0	1
Interval between transfusions		
1 day	1	4
2 days	2	10
3 days	3	2
More than 3 days	2	4

The hemostatic effectiveness of later transfusions as compared with that of the first appeared to be less in patients of group B than in those of group A. Group B included two patients in whom no effect was evident after either the initial or subsequent transfusions. The degree of hemostasis after repeated transfusions was considered less than after the first transfusion in one group A and five group B patients, the same in two group A and two group B patients, and greater in one group A patient; whether there was a change was not determined in one group A patient.

Use in Surgery.—A platelet transfusion was used prophylactically as a preoperative measure in nine patients. In five it was the only transfusion given, and in four severe bleeding had first been controlled by previous platelet therapy. Seven patients had splenectomy, one had nephrectomy, and one had hysterectomy. In all except one these transfusions were completely effective; at no time did the bleeding at operation cause the surgeon any concern. Platelet transfusion was ineffective in the patient in whom hysterectomy was done; she had chronic granulocytic leukemia and was in a terminal state. A spleen weighing 3,500 gm. was removed from the patient with Gaucher's disease; the procedure was described as "dry" and uneventful.

Transfusion Reactions.—Transfusion reactions occurred in six patients, three of each group. They ranged

[2] Geiger, J.: Thrombocytopenic Purpura Induced by Sulfisoxazole (Gantrisin) Therapy: Report of Case Controlled by Platelet Transfusion, J. A. M. A. 149: 1219 (July 26) 1952.

in severity from mild fever on the day after the transfusion was given to chilly sensations and a feeling of constriction in the head, chest, or low back shortly after the start of the transfusion, followed by a shaking chill and high fever. Only one patient had had a previous platelet transfusion, and two others had a history of reactions to previous blood transfusions; all three had a history of allergic manifestations. In the three other patients, none of these possible causes was operative; in one the transfusion was interrupted for a few minutes at the onset of the reaction and then was given more slowly, without further untoward effect. Platelet transfusions achieved their purpose completely in two of the six patients in whom there were reactions and partially in a third patient. In none of the 14 patients who died within two weeks after a platelet transfusion was the transfusion considered to be a contributing cause. Autopsy was performed on five, and no evidence of thrombosis or embolism was found.

Discontinuation of Transfusions.—Platelet transfusions usually were discontinued in patients of group A when a spontaneous or postsplenectomy remission occurred. One of the two deaths in this group occurred in a 2-year-old child as the result of fulminating septicemia, and the other resulted from a cerebral vascular accident that occurred 12 hours before platelets were given. In group B, most of the patients were in a terminal state, and the outlook was too grave in some cases to justify further transfusions; oftener, death supervened, despite improvement in the bleeding tendency. The following tabulation shows the reason for discontinuation of platelet administration in both groups:

	Group A	Group B
Purpose accomplished	4	0
Purpose accomplished, but prognosis poor	0	4
Splenectomy done	7	0
Patient died	2	7
Transfusion reaction occurred	1	1
Transfusions not effective	0	2

Evaluation.—The over-all evaluation of the effectiveness of transfusions of platelet concentrates, summarized in the tabulation below, indicates that they were frequently effective in both groups but were effective oftener in group A.

	Group A	Group B
Life-saving	5	0
Life-prolonging	2	4
Beneficial	6	5
Without effect	0	4
Somewhat harmful (transfusion reaction)	1	1

COMMENT

The patient with thrombocytopenia is threatened with death from possible internal hemorrhage. At any time, bleeding may become either so generalized or so sudden and massive as to preclude adequate replacement of blood, or a fatal cerebral vascular accident may occur. The potential danger varies with the severity of the bleeding and with the likelihood that it will cease spontaneously; these, in turn, depend on the pathogenetic mechanism responsible.

When critical bleeding is present or incipient, its prompt control is indicated. It is logical to attempt platelet replacement therapy in thrombocytopenia. Large numbers of platelets may be transfused by the use of platelet-rich polycythemic blood, fresh blood at frequent intervals, or platelet concentrates derived from several pints of normal blood. Improvement in hemorrhagic manifestations usually follows the transfusion of polycythemic blood[3]; such blood may not, however, be available when needed, and some physicians hesitate to use it. Fresh blood may have a hemostatic effect[4]; however, its use in large volume is limited by the functional capacity of a heart possibly already weakened by myocardial hemorrhages; in some instances, even the direct transfusion of 1,500 ml. of fresh blood is of little benefit.[5] Transfusion of platelets separated from normal blood and concentrated in a small volume of physiological fluid provides an alternative method for producing hemostasis.[6]

The composite experience reported here indicates that platelet concentrates are useful in the symptomatic control of thrombocytopenic purpura, regardless of the underlying cause. They have been of most value in cases in which critical bleeding was present or its occurrence was threatened but the ultimate prognosis was good. They have been used as supportive treatment for patients with severe but temporary depression of bone marrow function, and their use has permitted safe splenectomy in patients with idiopathic thrombocytopenic purpura with severe bleeding. In cases in which the marrow was aplastic or extensively invaded by leukemic cells, however, the usefulness of these transfusions has been limited by the necessity of giving several each week. Repeated transfusions have succeeded in prolonging life, but large supplies of blood have been required, and there has often been a progressive decrease in hemostatic effectiveness, presumably because of the development of antibodies to the transfused platelets.[7] Transfusion reactions occasionally have been encountered; the possibility of such a reaction does not seem to justify withholding platelet transfusion therapy when it is indicated.

The mechanism by which transfused platelets exert a hemostatic effect is unknown. It has been observed that large numbers of transfused platelets disappear promptly from the circulation; the improvement in the bleeding tendency generally persists, however, for many hours to several days after the platelet count has returned to its pretransfusion level.[8] This would suggest that the vascular defect that causes the clinical manifestations of purpura must be corrected, temporarily, either by intact platelets withdrawn from the circulation or by products elaborated by them or resulting from their disintegration.

SUMMARY

Clinical experience with 57 transfusions of platelet concentrates in 28 patients with thrombocytopenic purpura is reviewed. These concentrates were prepared from normal blood and were given to control active bleeding or to assist hemostasis at surgery. Their use usually was followed by a beneficial effect, which generally lasted from one to several days. Platelet transfusions were most useful in cases of idiopathic thrombocytopenic purpura as a prophylactic measure prior to splenectomy and as supportive therapy in cases of thrombocytopenia secondary to severe but transient depression of the bone marrow.

TRAUMATIC AUTOPLASTIC IMPLANTS OF SPLENIC TISSUE

C. Hartley Berry, M.D.
and
George L. Erdman, M.D., Summit, N. J.

Occasional reports have appeared over the last 40 or 50 years describing multiple, purplish-red nodules of varying size scattered throughout the abdominal cavity in persons who almost invariably had a history of splenic trauma requiring splenectomy. These nodules grossly resembled splenules and were found, on microscopic examination, to be composed of splenic tissue. Since 1939, when Buchbinder and Lipkoff[1] first suggested its use, the term "splenosis" has been employed to refer to this condition and to imply that the nodules are implants of splenic fragments.

There has never been any real doubt that these nodules are splenic tissue, but their pathogenesis has not been entirely settled. Some of the earlier investigators held that these spleen-like nodules developed after splenectomy as compensatory enlargements of persistent splenic anlagen of phylogenetic origin, since certain of the lower animals normally have splenic tissue distributed throughout the intestine instead of having a single organ. Others suggested the possibility of a compensatory hyperplasia of accessory spleens.

This theory of compensatory hypertrophy is partially discounted by the fact that autoplastic transplants of spleen readily survive in various experimental animals. Kreuter[2] and later, Putschar[3] both demonstrated the ease with which fragments of splenic pulp become engrafted when seeded into the peritoneal cavity of an animal. Jarcho and Andersen,[4] while conceding that further studies of splenosis are necessary, state: "Even now it is scarcely possible to avoid the conclusion that the intraperitoneal nodules found after splenectomy in cases of splenic rupture are due to the scattering of particles of pulp throughout the peritoneal cavity." We accept this as a reasonable conclusion.

In view of the relative frequency with which traumatic rupture of the spleen occurs, it is strange that splenosis is so rarely encountered. Waugh,[5] reporting a case in 1946, reviewed the European and American literature and found only 16 cases with previous history of splenic trauma. To these can be added one reported by Bunch and Spivey[6] in 1946. In 1947, Stobie[7] published the first report of splenosis following splenectomy for nontraumatic reasons (thrombopenic purpura). Splenosis was discovered at a second operation following the return of purpuric manifestations after a period of remission. Although there was no antecedent history of trauma in this case, there was probable spillage of splenic pulp at the time of the splenectomy, since the report concluded with an admonition that rupture of the spleen be avoided during the performing of splenectomies. In 1950 Sampaio[8] reported another case of splenosis following traumatic rupture. Since the number of reported cases is extremely small, it seems worth while to report an additional case of splenosis with the hope that others will be stimulated to report similar cases. In this way a more accurate estimate of the actual incidence of splenosis may be obtained.

REPORT OF A CASE

In March, 1949, a 12-year-old white boy was subjected to a splenectomy because of a traumatic rupture of the spleen. Convalescence was uneventful. Approximately one year later an appendectomy was performed. Nothing unusual was noted in the area of the peritoneal cavity exposed by the laparotomy. The pathological diagnosis at that time was lymphoid hyperplasia of the appendix. In March, 1951, almost two years after the splenectomy, a third laparotomy was necessary for the relief of symptoms of obstruction in the gastrointestinal tract. The onset of symptoms at first suggested a mild upper respiratory infection such as was prevalent in the community at the time; but when the patient was examined by one of us, the clinical findings were those of partial bowel obstruction. The child was admitted to the hospital for study and definitive care. Roentgenograms revealed evidence of intestinal obstruction in the distal jejunum or proximal ileum. The exact nature of the lesion was not apparent from the roentgenograms, but, from the history of the case, it seemed most probable that postoperative adhesions were causing the obstructive symptoms. At operation, as was expected, an adhesive band causing partial obstruction was found. This band, which was approximately 5 cm. long, was attached to the antemesenteric border of the jejunum 12.5 cm. below the ligament of Treitz and reached to a more distal segment of the jejunum, where it was adherent to the mesenteric border. Loosely caught between this band and the jejunum was a loop of proximal ileum. The serosal surface was engorged, indicating some circulatory embarrassment, but on resection of the band the bowel quickly regained its normal color. In addition to the band, a number of small, purplish-red nodules were noted. The largest nodule, about 5 mm. in diameter, was adhered to and partly incorporated in the upper end of the obstructing band. Smaller nodules scattered in the same general area were attached to the serosa

of adjacent loops of bowel, to the mesentery, and to the omentum. Several of the larger nodes were excised for microscopic sections. When the nodules were seen at operation, it did not occur to us that they were splenic implants; it was only after microscopic examination that these lesions were identified. After operation the patient recovered rapidly and has remained well.

COMMENT

There are no specific symptoms in splenosis. The diagnosis of the condition appears never to have been made preoperatively; the usual diagnosis is chronic appendicitis or intestinal adhesions. Splenosis, per se, is of no great pathological importance except in hematological conditions requiring complete removal of splenic tissue. Adhesions resulting from the original trauma or from subsequent surgery are the chief concern, as seen in this case of partial bowel obstruction. It does seem, however, that a tentative diagnosis of splenosis with adhesions could be made in patients who have previously undergone splenectomy and who present vague abdominal symptoms at a subsequent time. At least, the surgeon should be able to recognize the condition when it is found at operation, which we failed to do. In a woman, splenosis could be mistaken grossly for endometriosis, but the clinical history and the rhythmical exacerbation of symptoms in the latter condition would be determining factors in a differential diagnosis.

In traumatic cases in which splenectomy is required, a knowledge of the probable pathogenesis of splenosis should suggest to the surgeon a thorough search for and removal of even the smallest fragments of splenic pulp. As far as is possible, all free blood, which may contain splenic pulp cells, should be sponged from the peritoneal cavity.

129 Summit Ave. (Dr. Berry).

Accidents—The Preschool Child's Greatest Hazard.—Accidents constitute the greatest single threat to the lives of children 1 to 4 years of age. About 5,500 deaths, or one quarter of the total that occur annually among preschool children result from mishaps of one kind or another. . . . Although the relative importance of accidents in the total mortality picture increases during the early years of life, the death rate from accidental injury actually decreases from age 1 through 4. This simply means that during the preschool ages the chances of death from accidental injury decrease less rapidly than the chances of death from disease. . . . About two fifths of the deaths from the various types of accidents among insured preschool children in the United States occur in the home. . . . It is apparent, therefore, that the success of the safety program for youngsters will depend in large measure on the effort that parents make to reduce the hazards in the home and keep constant watch over young children. The physician, and particularly the pediatrician, also has an important role to play in the child safety program. As a family counselor he has the opportunity and the responsibility to advise on accident prevention. The physician is familiar with the child's growth and development, and can therefore enlighten parents on hazards against which reasonable precautions should be taken at various stages of development. A program of safety education begun in the preschool years by an interested physician and receptive parents can be the foundation for safe practices which may last throughout life.—Accidents—The Preschool Child's Greatest Hazard, *Statistical Bulletin*, Metropolitan Life Insurance Company, May, 1953.

MANAGEMENT OF GASTROINTESTINAL HEMORRHAGE OF UNDETERMINED ORIGIN

VALUE OF IMMEDIATE EXPLORATORY LAPAROTOMY DURING ACTIVE BLEEDING

H. L. Bockus, M.D.
L. K. Ferguson, M.D.
C. Thompson, M.D.
and
J. L. A. Roth, M.D., Philadelphia

This case is reported to illustrate a principle that has proved of value in the management of massive hemorrhage from the gastrointestinal tract in cases in which the cause of bleeding cannot be discovered by exhaustive studies. In such instances, we believe that exploratory laparotomy should be looked on as a diagnostic procedure, but, to discover the bleeding site, the operation must be performed during the episode of active bleeding. The frequency with which the origin of manifest gastrointestinal hemorrhage is not revealed by meticulous and comprehensive studies varies considerably in reported series (from 2 to 30%). The explanation for this may lie in one or more of the following factors: (1) an inaccurate or incomplete history; (2) overlooking a significant physical finding; (3) incomplete or inaccurate laboratory observations on liver function, blood dyscrasias, and bleeding mechanisms; (4) inadequately performed roentgen studies of the gastrointestinal tract, e. g., failure to carefully study the lower esophagus, lack of utilization of special techniques for the demonstration of hiatus hernia, lack of use of compression films and special projections in the study of the stomach or duodenum, presence of nonopaque residue or blood in an ulcer crater, inadequate study of the mesenteric small intestine without resort to compression, or improper preparation of the colon for barium enema or failure to obtain postevacuation or double contrast films; (5) failure to consider unusual causes of hemorrhage and failure to direct investigation along the lines necessary to disclose such causes; (6) failure to employ "early" roentgen study, gastroscopy, or esophagoscopy in selected cases of recurrent bleeding (the "early" use of the Einhorn string test may help in determining whether the level of bleeding is between the esophagus and the ligament of Treitz).

When the bleeding is characterized by hematemesis, the bleeding point may be fairly well localized to the upper gastrointestinal tract between the esophagus and upper jejunum. The bleeding that appears only as melena (tarry or red stool) is more difficult to localize, since it may arise from a lesion anywhere from the esophagus to the rectum. One may attempt to judge the level of the bleeding point by the color of the blood in the stool, but the color change from bright red to dark cherry red to black varies not only with the level of the bleeding point but also with the rapidity of bleeding and the speed of intestinal transport. Hence, stool color is not always a reliable guide and may be misleading.

From the departments of gastroenterology (Drs. Bockus and Roth) and surgery (Dr. Ferguson), Graduate Hospital of the University of Pennsylvania, and the Department of Gastroenterology (Dr. Thompson), Hahnemann Medical College and Hospital.

Despite the use of great care in performing comprehensive studies, there are a number of patients (about 10 to 15%) in whom no cause for hemorrhage can be found. In such instances, we believe that exploratory laparotomy should be looked on as a diagnostic procedure. The more frequently abdominal exploration is employed, the more likely is it that superficial ulceration or erosive gastritis, small bowel tumors, or unusual vascular or other rare lesions will be encountered, thus reducing the incidence of undetermined causes.

The bleeding may stop during the period taken up by the study of the patient, or frequently the patient is first seen during a free interval. Operation at this time, without a definitive diagnosis, often results in an unproductive exploration. Even with careful inspection and palpation of every inch of small and large intestine, nothing may be found, and there is nothing to guide the surgeon to the site of the lesion. If bleeding has stopped, and the cause has not been discovered, it is advisable that exploration be deferred, because an unfruitful exploration often makes a subsequent procedure more difficult. In selected patients in whom available objective studies have failed to disclose the cause of bleeding, it has been found more productive to do an exploration as soon as possible after a recurrence of bleeding becomes manifest and the patient has been brought out of shock and the blood volume replaced by immediate transfusion. Exploration should be accomplished during active bleeding, without the delay of repeated studies. The appearance of the upper level of blood in the intestinal tract may mark the site of the bleeding. A delay of only a few hours may result in a loss of this advantage, since the bleeding may temporarily stop, and peristalsis may rapidly clear the intestine of its blood content. To fulfill the rigid criteria for management of such cases, the patient is advised to come to the hospital immediately, with the first sign of blood loss. The surgical service should have a record of the possible admission of such a patient in order that preparation for immediate operation may be instituted at once. The following case report is illustrative of such an experience.

REPORT OF A CASE

A. L., a 75-year-old retired businessman, was admitted to the Graduate Hospital on May 5, 1951, for the study of recurrent episodes of rectal bleeding and melena. Bright red, blood-streaked, formed stools were passed periodically for one year prior to November, 1949. At that time, he began to have severe rectal bleeding, with the passage of several tablespoonsful of bright red blood and momentary loss of consciousness. He was hospitalized elsewhere and required a single transfusion of whole blood. For three or four days thereafter, he passed tarry stools. The sequence of bright red rectal bleeding followed by melena was repeated in August, 1950, February, 1951, March, 1951, and in early April, 1951. In the interval between these severer bleeding episodes, the stools were normal in character and consistency, except for streaking of bright red blood occasionally, attributed to hemorrhoids. Constipation with the passage of scybalous stools and increased necessity for straining usually preceded the more vigorous bleeding for several days. The patient was conscious of gaseousness and borborygmi for several hours as a forewarning of the impending rectal hemorrhages. He denied having abdominal pain of any kind, rectal tenesmus, or abdominal distension with any of these attacks. His appetite remained good and his food intake adequate. Vigor had been maintained, and the patient felt well between the episodes of bleeding. He estimated he had had a gradual weight loss of 8 lb. (3.6 kg.) during the 18 months following his first hemorrhage. Other bleeding tendencies were denied, and the family history was negative for blood dyscrasias. A systemic review was noncontributory.

The patient had been hospitalized again in February, 1951, and required five blood transfusions (2,500 cc.) to restore the red cell count to normal. The hemorrhage in March, 1951, was associated for the first time with nausea but not with vomiting or hematemesis. During the various hospital admissions elsewhere, the patient was studied repeatedly by barium enema and barium meal studies, sigmoidoscopy, and laboratory studies for bleeding dyscrasias, but no cause for bleeding was discovered. After an inconclusive exhaustive investigation in March, 1951, during a quiescent interval when there was no evidence of active bleeding, an exploratory laparotomy had been performed, but the site of previous hemorrhages was not revealed.

The episode of rectal bleeding that culminated in the patient's transfer to the Graduate Hospital began on April 25, 1951, and was different from previous attacks in that melena persisted longer (8 days). Four blood transfusions were administered at another institution prior to the transfer.

The patient appeared younger than his stated age; he was undernourished and of asthenic habitus. The skin was clear except for scattered senile keratoses; no significant accessible lymphadenopathy was encountered. There were no petechiae or ecchymoses, and the mucous membranes revealed no evidence of avitaminoses. Chest expansion and excursion were of good amplitude and equal bilaterally, and the lungs were clear to percussion and auscultation. The heart was not enlarged to percussion; a grade 2 systolic murmur was audible. Blood pressure was 114/60 mm. Hg and the pulse rate 88 beats per minute, with a regular sinus rhythm. The abdomen was scaphoid in contour, and the scar from the previous laparotomy was well healed. There was no abdominal distention, and the bowel sounds were of normal quality and frequency. The liver, kidneys, and spleen were not palpable. Rectal examination disclosed external hemorrhoidal tags, and the prostate was firm, symmetrical, and smooth and only slightly enlarged. No Blumer's shelf was encountered, and the ampulla was full of soft brown feces, which were 4+ for occult blood (Gregersen). Results of sigmoidoscopy were normal. The initial red blood cell count was 3,770,000 per cubic millimeter, with 9.5 gm. of hemoglobin per 100 cc.; the white blood cell count was 5,600 per cubic millimeter, with a normal differential count; the platelet count was 540,000 per cubic millimeter; the coagulation time was 2 minutes, the bleeding time 3 minutes, and the prothrombin time 17 seconds (85%). Results of liver flocculation tests were normal; the serum bilirubin level was 0.2 mg. per 100 cc., and sulfobromophthalein (Bromsulphalein) sodium retention was 0.8% (5 mg. per kilogram of body weight in 45 minutes). Results of routine urinalysis were essentially normal; the urine had a specific gravity of 1.014. The stools were dark brown in color and gave a 4+ reaction for occult blood for eight days following admission. A Rumpel-Leede capillary fragility test revealed 17 petechiae in the antecubital space (2.5 cm. circular area). X-ray studies after a barium enema showed several small diverticula in the proximal sigmoid colon but otherwise revealed no abnormality. A satisfactory mucosal pattern was obtained, especially in the cecum and ascending colon. The barium meal study revealed a small sliding hiatal hernia but no evidence of peptic ulcer disease, tumor, or Meckel's diverticulum. The mesenteric small intestine appeared normal. At a time when there was no longer evidence of bleeding into the gastrointestinal tract, an Einhorn string test was negative.

The failure of these and previous studies elsewhere to disclose the site of gastrointestinal bleeding was discussed with the patient, and the recommendation was made that, if bleeding should recur, he be hospitalized immediately, given transfusions to replace blood loss, and, without further study, be subjected to exploratory laparotomy during active bleeding. He was discharged on a bland, low residue diet, with prune juice to aid bowel movement. One week following discharge from the hospital, on May 27, 1951, he had a recurrence of rectal bleeding several minutes after passing a normal stool.

The second bowel movement consisted of bright red blood and dark blood clots. He was hospitalized immediately, according to previous arrangements. On admission, examination revealed no additional findings, except for the presence of dark red, bloody material in the rectum. Vital signs were essentially unchanged.

The patient was taken immediately to the operating room, where one of us (L. K. F.) explored the abdomen to search for the bleeding site. The peritoneal cavity, which had been opened previously, showed the presence of multiple adhesions, and the small bowel loops were adherent to each other. It was necessary to free the entire mesenteric small bowel from adhesions to exclude the presence of a lesion. The stomach and duodenum appeared normal, and no lesion could be palpated. The appearance of the small intestine and colon presented a striking contrast because of a bluish discoloration extending from the cecum down to the rectum, attributed to blood within the lumen of the colon. A similar but less definite discoloration was noted in the most terminal segment of the ileum.

The distal ileum was opened to determine whether blood was coming from above or from the terminal ileum. By aspiration proximally, normal, bile-colored fluid coming down from above was recovered, whereas when the aspirator was inserted distally some blood was obtained. No lesion could be palpated on insertion of a finger into the terminal ileum. The cecum was opened, and a considerable amount of old blood was encountered, which was aspirated. The cecum was turned inside out for a close inspection. The ileocecal valve appeared normal, and no bleeding point was visualized. In the cecum there was a dark red, rosebud-like lesion, measuring 3 mm. in diameter, resembling an hemangioma with a white fleck in the center. Vigorous pulsatile bleeding occurred after the lesion was wiped with a sponge. Two pulsating vessels were present at this area. About 3 cm. away, along the ascending colon, were two similar lesions, and two small pedunculated, nonbleeding polyps (2 and 4 mm.) were found in the hepatic flexure area. A right hemicolectomy was performed with ileotransverse colostomy, using an end-to-end anastomosis.

The surgical specimen revealed a small, dark red lesion in the cecum, having the appearance of a "blood blister" and measuring 2 mm. in diameter. Two lesions similar in size and appearance were present in the ascending colon, as well as two small pedunculated polyps, measuring 2 to 4 mm. in diameter. Histologically, the latter were benign adenomatous polyps. Microscopic section of the hemorrhagic lesions revealed a minute hematoma covered by hemorrhagic mucosa, the extravasation of blood being limited to the submucosa. Multiple sections failed to conclusively demonstrate a hemangioma or arteriovenous aneurysm, and the lesion was interpreted as submucous telangiectasia. Nineteen months have elapsed since the operation was performed. There have been no further bleeding episodes.

COMMENT AND CONCLUSIONS

It is inconceivable that any type of diagnostic study would disclose a lesion of the type in this case. Careful exploration of the entire alimentary tract had been performed by a capable surgeon previously but at a time when hemorrhage was not occurring. A guide to the possible site of bleeding was afforded at the time of our exploration by visualization of the upper limit of discoloration of the bowel by bloody content. Nothing could be palpated. It was only when the cecal area was turned inside out that the small "spurter" was seen. Performance of an operation during a bleeding episode is no longer attended by great hazard. When all diagnostic aids have failed to disclose the cause of massive bleeding episodes, operation during the course of the next episode of massive bleeding should be considered as the procedure of choice.

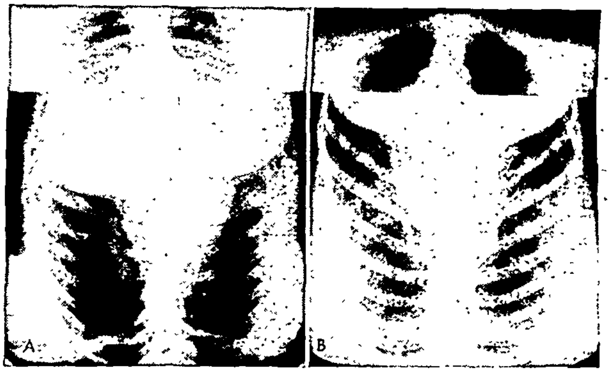
TECHNICAL MODIFICATION OF ROUTINE CHEST RADIOGRAPHS

Robert W. Currie, M.D., Marion, Ind.

The average roentgen image of the thorax does not completely fill a 14 by 17 in. radiograph. Approximately 4 in. of the film is noninforming in the subdiaphragmatic and superclavicular areas. Many European radiologists use 14 by 14 in. radiographs for chest work. I have copied their technique, but use a standard 14 by 17 in. film and cassette instead. Survey sagittal chest radiographs have three important blind spots: the posterior subdiaphragmatic area, the retrocardiac area, and the apical areas hidden by the clavicles and first ribs. Lateral radiographs of the chest will visualize the first two, but it takes a lordotic view to adequately visualize the apical lung fields in certain body builds.

Study of lordotic radiographs of the chest show that their value is confined mostly to the upper one-fifth of the thoracic cage, and that below this the overlap of lung markings obscure radiographic detail. By the use of sheet lead shielding and special attention to patient positioning, both the conventional sagittal radiograph and the apical lordotic view can be obtained on the same 14 by 17 in. radiograph. The marginal 3 or 4 in. not utilized by the thoracic shadow is sufficient to record the apical lordotic image (see *A* of the figure). A piece of masking lead is cut to fit the front of the cassette holder so that the lower 4 in. of the radiograph is not exposed. With this lead in place the conventional sagittal radiograph is taken. The cassette is then turned end for end (or upside down), and a larger piece of masking lead to cover the initially exposed film area (14 by 13 in.) is placed in the front of the cassette holder. The patient is then placed for the lordotic view in the anterior posterior position with the dorsal spine hyperextended, the shoulders rolled forward, and the feet about 12 to 18 in. away from the base of the cassette holder.[1] If the line formed by the superior margin of the clavicle is on a level with the upper film margin, the positioning is usually satisfactory.



Radiographs of the chest, utilizing sheet lead shielding and careful patient positioning. *A*, image showing both the conventional sagittal and the apical lordotic view. *B*, image showing an apical parenchymal density not usually visible.

---

[1] Sante, L.: Manual of Roentgenological Technique, ed. 13, Ann Arbor, Mich., Edwards Brothers, Inc., 1946, pp. 191 and 192.

Close scrutiny of a large number of sagittal chest radiographs emphasizes that focal pathology can be obscured by the bony overlap of clavicle and first rib. Patton and Badger[2] call the lordotic view a refinement of radiological technique and nicely demonstrate its value in their discussion of pulmonary tuberculosis. The figure (*B*) also demonstrates an apical parenchymal density not visible in the routine sagittal position. Certainly the added time and effort needed to routinely record the apical lordotic view is justified to eliminate this blind spot on survey chest radiographs.

EASY REMOVAL OF SKIN SUTURES

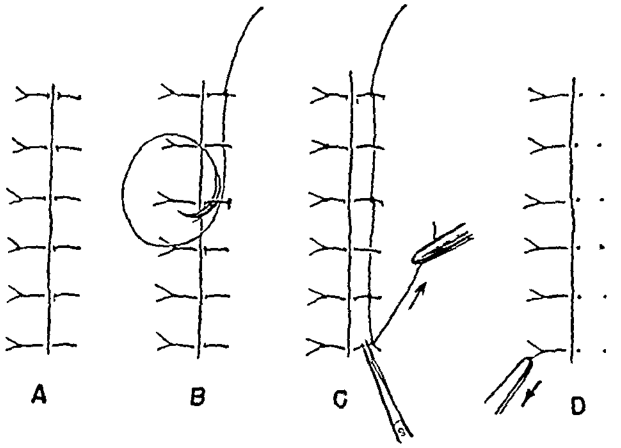
Mandel Weinstein, M.D.
and
Morton Roberts, M.D., Jackson Heights, N. Y.

The removal of skin sutures may be as much of an ordeal for the physician as for the patient. In this modern era of almost unbelievable surgical techniques and skills, one still hears a lay person remark that "the removal of my sutures was a more painful experience than the operation itself." We wish to describe a "suture lift" that will facilitate the removal of skin sutures. This "suture lift" consists of a separate piece of nonabsorbable surgical suture threated under all of the stitches after their insertion and fixed to some of them. Traction upward on one end of this thread permits easy visualization of all the skin sutures for incision and extraction.

The removal of ordinary over-and-over interrupted or continuous skin sutures presents no serious problem since each loop is usually exposed enough to be cut with the tips of scissors. Difficulty is encountered, however, in removing such sutures if they incorporate very small bites of skin or are made of extremely fine material. As the more popular method of skin approximation is the Stewart or vertical mattress suture, the "suture lift" has been devised to remove that type. This method of wound closure is considered more effective because it allows more precise approximation of the skin edges, a securer closure, the elimination of underlying dead space, and a better cosmetic result. A properly inserted Stewart suture is made with a spear-pointed needle and consists of two parts. First, the operator stitches the skin edges intradermally as close to the incision as possible. Then, by reversing the direction of the needle and by moving a distance from the wound edges, the needle is passed through the skin and subcutaneous tissues of both sides. Finally, the ends of the suture are tied, resulting in a loop on one side of the wound and a knot on the other.

The method usually advised for removing Stewart sutures is to insert a scissors blade under the loop, cut the suture, and remove it by pulling the knot or free ends on the knot side of the incision. The normal healing processes of operative wounds, however, often make this procedure very difficult. Postoperative edema and swelling may cause the suture to be so depressed and buried in the skin that delivering it for severance may be almost impossible. If very small sutures are fashioned or if the suture material is very fine, the procedure may be extremely difficult and very painful. Should the incision be placed between skin folds or crease lines, as in saphenous vein ligations in the subinguinal region, the difficulties that may be encountered are obvious. As a matter of fact, the idea of a "suture lift" was first conceived when an attempt was being made to remove almost completely buried nonabsorbable sutures from an obese woman who had had an inguinal incision for a varicose vein operation.

The "suture lift" is applied in the following manner. After all the Stewart sutures have been inserted, a small, curved round needle is threaded with 3-0 nonabsorbable surgical suture and passed around the loop of the first stitch and the thread tied. The free end is cut approximately 2 in. (5.08 cm.) long. The thread is then passed under the loop of the second stitch and around the loop of the third stitch. This procedure is repeated so that every other stitch is fixed to the "suture lift" by an extra turn of the thread, as indicated (see figure). The procedure is terminated by locking the thread to the last suture; thus, it is fixed at both ends.



A, appearance of the wound with the usual Stewart sutures in place; *B*, insertion of the "suture lift"; *C*, cutting of the loops of the sutures made easy by upward traction on the "suture lift"; and *D*, removal of cut sutures.

After a week, removal of the Stewart sutures is easily accomplished by grasping one end of the "suture lift," maintaining steady traction away from the skin surfaces, and cutting each loop as it is lifted out of its bed. Loops of fine thread that have become deeply buried in the skin may be raised easily and cut. After cutting all the loops, it is a simple matter to remove the sutures quickly by pulling the knotted ends on the opposite side of the incision. The appreciation expressed by the patient for the quick and relatively painless removal of the sutures will more than repay the surgeon for the additional minute or two consumed in the insertion of the "suture lift."

75-17 41st Ave. (Dr. Weinstein).

COUNCIL ON PHARMACY AND CHEMISTRY

REPORT TO THE COUNCIL

The Council has authorized publication of the following report from the Committee on Pesticides.

R. T. Stormont, M.D., *Secretary.*

Initial reports of success in the control of flying insects in enclosed spaces led to the introduction of a multitude of electric and other types of devices employing heat for the release of insecticides into the atmosphere of homes and other places of human occupancy. Although many of them were poorly constructed, they were promoted for nearly every conceivable domestic insect control problem. Medical concern for the safety of these contrivances, especially for home use, prompted the Committee on Pesticides to publish a report, "The Health Hazards of Electric Vaporizing Devices for Insecticides" (J. A. M. A. 149:367 [May 24] 1952). The Committee's report furnished a compelling argument for the need of caution and control in the use of vaporizing equipment. Since the publication of this statement, new devices and new regulations have appeared and new cases of injury have been reported. The Committee feels that these and other changes that have occurred warrant a supplementary report on the health problems of this type of insect control.

Bernard E. Conley, *Secretary*
Committee on Pesticides.

HEALTH PROBLEMS OF VAPORIZING AND FUMIGATING DEVICES FOR INSECTICIDES

A SUPPLEMENTARY REPORT

Dispensing insecticides into the atmosphere of buildings and other enclosed spaces principally for the control of flying insects is being exploited in a variety of ways. Among the methods being critically examined for their health hazards are those concerned with heating, igniting, or otherwise evolving vapors or fumes of chlorinated hydrocarbon insecticides. Two types of applications are currently employed: the slow, continuous dispersion of insecticide vapor in occupied areas other than homes and food handling establishments, and, conversely, the rapid release of insecticidal fumes in temporarily unoccupied areas at intervals not to exceed every other week. Applicators utilized for these operations are now commonly referred to as insecticide vaporizing and fumigating devices, respectively.

VAPORIZER REGULATIONS

Official acceptance of the methods embodied in these applications have undergone considerable modification in the last two years. Recommendations covering the chemicals used in these devices, their construction, and conditions under which continuous-type thermal generators for insecticides could be used were issued in September, 1951, by the Interdepartmental Committee on Pest Control, a group representing federal agencies interested in pest control. At that time, it was recommended that only dichlorodiphenyltrichloroethane (DDT), gamma benzene hexachloride (lindane), or their mixtures should be used at a rate not to exceed 1 gm. to 15,000 cu. ft. in 24 hours. The use of units with protective features to indicate times of operation and to prevent excessive output, plus instructions for installation in positions above head level and away from situations favoring food contamination, were outlined. Warning also was given against use in homes and sleeping quarters or in other places where continuous prolonged exposure was possible.

A subsequent report by the Committee on Pesticides gave substance to these recommendations by furnishing supporting laboratory data and cases of injury during servicing and operation of vaporizers in homes, offices, public eating places, and industrial establishments. The Committee pointed out that the vast majority of devices in use, because of poor construction and improper installation, violated accepted health practices. Attention was called to the urgency of this problem, and the Committee suggested that further steps be taken, at the state and local level, to curtail uncontrolled use. At least 14 states and 35 municipalities have since adopted measures controlling the installation, sale, or use of these devices. Other states and local groups have invoked existing provisions of their food laws and sanitary codes for similar purposes.

Further control governing the use of this type of insecticide volatilizing apparatus was recommended in a second release of the Interdepartmental Committee on Pest Control, Oct. 22, 1952. This statement superseded and expanded earlier recommendations for the safe use of continuously operating types of vaporizing equipment, particularly with respect to uniformity of output and use in food handling establishments. It reiterated previous warnings against home use or prolonged use in other environments and further advised against placement of vaporizers in areas where food is processed, served, or stored, unless it can be shown that contamination does not occur. The Interdepartmental Committee reaffirmed its recommendation for a maximum dispensing rate of 1 gm. per 15,000 cu. ft. in 24 hours; however, it restricted variation in output to 25% of the dispensing rate per hour. No suggestions were made about construction of the devices other than to advise that they should be so built that output in excess of that recommended is impossible. Although the Committee's recommendations have no binding legal effect, acceptance of these recommendations in new or amended state or local regulations provides direct control over vaporizers. By contrast, existing federal legislation has only an indirect influence since jurisdiction is restricted to the chemicals employed (Insecticide, Fungicide, and Rodenticide Act, 1947) or to situations in which food products may become contaminated (Food, Drug, and Cosmetic Act, 1938).

This release of the Interdepartmental Committee places the responsibility for demonstrating the efficiency and safety of insecticide vaporizers on the manufacturer or his agent and, at the same time, provides enforcement officials with a broad basis for rejecting or removing unacceptable equipment. Explicit directions for applying the proposed restrictions have not been outlined, in view of the obvious limitations of such a procedure. Precise requirements for equipment construction to allow accurate measurement of operating temperature and output were not prescribed because of uncontrollable environmental influences such as ventilation characteristics or the nature of the exposed surfaces in various treated areas. Since air concentration does not have a simple relationship to the amount of insecticide dispersed, tolerances for an atmospheric concentration of insecticide were not defined. They would likewise be unsuitable for judging the safety of installed apparatus other than for testing operating efficiency. Specific analytic methods for determining and distinguishing between small amounts of insecticides and other materials normally present in suspected food products could not be advised because available methods are not sufficiently convenient, sensitive, or discriminating for all purposes to which they might be applied. The use of spectrophotometric methods for detecting DDT or lindane have been suggested for this purpose in laboratories with sufficient personnel and equipment to perform these intricate analyses.

TECHNICAL DEVELOPMENTS

New requirements for the construction and installation of insecticide vaporizers were issued because field experience had shown that the previously established standards for safe and effective use were not entirely satisfactory. Many devices purportedly embodying the constructive features advised in the original release were still found in practice to vary widely in output and other types of performance. Since potentialities for harm are, in part, correlated with the degree that equipment varies from the recommended standards for release of the insecticide, stricter definition of the performance characteristics became necessary. Misinterpretation or circumvention of present recommendations is virtually impossible concerning this point.

Equally restrictive are the recommendations for prohibiting use where food is processed, served, or stored. Laboratory studies have shown that various types of exposed surfaces differ considerably in their absorptive capacities to identical air concentrations of lindane that are well under the saturation level of the chemical in the atmosphere. Preferential absorption of lindane from the atmosphere has been observed by a variety of constitutionally dissimilar surfaces such as varnished wood, linoleum, plastic cheese wrappers, kraft paper, waxed paper, rubber sheeting, fatty and nonfatty foods, and water. The rate of disappearance of lindane from surfaces so contaminated is neither constant nor uniform.

The concentration of the insecticide and duration of exposure as well as the nature and extent of the surface exposed influence absorption. Preliminary laboratory studies have shown that 0.1 to 1 ppm or more per day will be absorbed by fruits, vegetables, cereals, dairy products, meat, bread, pastries, and other types of food exposed to vapors from a properly operating unit. Under similar conditions, water absorbs sufficient chemicals to be lethal to tropical fish. These findings, coupled with the observation that previous restrictions were not and cannot be practically enforced in other than industrial environments, prompted the current restrictions against use in food handling establishments.

The ban on the use of continuously operating vaporizing equipment in homes or other places where extended exposure is possible has been further justified by additional experimental and clinical findings. Chemical pneumonitis and minimal liver and kidney damage have been observed in several species of animals exposed to 0.7 mg. of lindane per cubic meter, seven hours a day for periods up to six months. This is between three and four times the maximum tolerated concentration of 0.2 mg. per cubic meter in the atmosphere; although it conforms to current specifications, it indicates a narrow margin of safety. When equipment is improperly operating or otherwise not adhering to specified conditions of use, a dangerous concentration of insecticide could be readily acquired that would not necessarily produce immediate signs of injury. It was also noted that the amount of lindane in the atmosphere may vary tenfold, depending on the ventilation rate in the treated area. Under certain conditions of minimal ventilation, air concentrations that may even approach saturation can be produced by a properly operating and installed device. This is highly undesirable because it increases the inhalation hazard to exposed persons and may cause gross contamination of exposed surfaces, including foods.

These restrictions should not be interpreted to mean that lindane does not have legitimate insecticidal use in vapor or other physical forms. It is accepted for general household use as a space spray (0.1%) and as a residual spray (0.5%) for spot application. The claim that it is discriminatory to accept these applications while prohibiting vaporizers in similar situations is without factual basis. Whereas certain of the accepted applications initially provide essentially the same atmospheric concentration of the toxicant as that provided by continuously operating types of vaporizers, atmospheric levels of lindane are maintained day after day at a fairly constant level only with the latter devices. Constant concentration and constant exposure characterize vaporizers, and for these and other reasons they are potentially more dangerous to those exposed. Other influences, such as their manner of promotion and widespread misuse, augment these basic factors and justify the attention that vaporizers have been given by health and regulatory officials.

CLINICAL EXPERIENCE

Opinion varies greatly as to the safety of vaporizing devices in human environment. Evidence in the majority of cases of injury suggests that defective equipment or other types of nonconformance with recommendations for use were primarily responsible; nevertheless, it is impossible to state that ill effects have not or will not result from properly operating devices used precisely in accordance with instructions.

Extensive use of these devices has demonstrated that human beings can acquire a sensitivity to lindane. In addition to cases cited in a previous Committee report, additional cases involving angioneurotic edema, skin sensitivity, and urticaria have been both privately reported and published.[1] Since allergy is neither a unique nor a uniform clinical condition, it is likely that similar cases have occurred that have not been brought to the attention of the Committee.

Local reactions involving varying degrees of irritation to the eyes and respiratory tract continue to be the commonest types of complaints. Coughing, sneezing, headaches, dryness or burning about the eyes, pain in throat and nostrils, nausea, and other nonspecific symptoms are among those noted. Single and multiple cases of such injury have been reported to the Committee from use of the devices in homes and in a bakery, garage, food mart, railroad restaurant, and other public gathering places.

Occasionally, severer local and systemic effects are reported that have a suspected or reasonably certain causal relationship with vaporizing equipment. In addition to the case of polyneuritis described in a previous Committee report, three cases of anemia, a near-fatal anuria, an asthma-like condition, and a severe and persistent tracheitis attributable to vaporizer exposure have also been brought to the attention of the Committee. With the exception of those conditions (asthma, tracheitis) in which symptoms were characteristic and the circumstances of exposure directly identifiable with periods of operation of the devices, it is impossible to determine whether illness was coincidental and unrelated or whether it was precipitated by constant exposure to vaporizer fumes.

The following case reports illustrate the complexity of the problem:

> In January, 1953, a 30-year-old woman experienced excessive tiredness and weakness four months after installation in her home of a portable electric insecticide vaporizer. During the next three months more frequent menstruation, menorrhagia, anemia, petechiae and purpura over the lower limbs, and periodic epistaxes appeared. The patient was hospitalized May 9, 1953, for an extreme anemic condition (with a hemoglobin level of 19%, 880,000 red blood cells and 3,400 white blood cells), and transfusions of whole blood were given. The report of physical examination, laboratory tests, and treatment based on the medical record of the research center to which she was transferred a week later was as follows:
>
> Exposure to lindane was continuous from September, 1952, through April, 1953. The only drugs the patient had received during this period were penicillin and oxytetracycline (Terramycin). A proprietary rug cleaner containing a small amount of trichlorethylene had been used on one or more occasions during the winter.
>
> The patient's blood pressure, pulse, and respiration were normal. Scattered petechiae were present on the buccal mucosa, posterior pharynx, and lower portion of the legs. She had bilateral retinal hemorrhages, but splenomegaly or hepatomegaly were not evident.
>
> When the patient was admitted on May 17, 1953, laboratory findings were as follows: hemoglobin level, 10.4 gm. (67%) per 100 cc.; red blood cell count, 3,600,000; hematocrit, 35; mean cell volume, 97; mean corpuscular hemoglobin concentration, 29.6; sedimentation rate, 12 mm. per hour; and white blood cell count, 3,600. The differential count showed 4 band neutrophils, 10 segmented neutrophils, 39 large lymphocytes, 40 small lymphocytes, 6 monocytes, and 1 eosinophil. The number of platelets was greatly reduced. Platelet count was 24,500 and reticulocyte count 1.1%.
>
> Urinalysis, stool examination, and tuberculin tests were negative. Liver function studies were entirely within normal limits. Sternal marrow was moderately cellular and of the type associated with hypoplastic anemia. Many young normoblasts were seen, and erythrocytic hyperplasia was found with an erythrocyte to granulocyte (e/g) ratio of 3:1. Many large proerythroblasts were present. Granulopoiesis was decreased, and mature forms were infrequent. Heavy toxic granulation was present. Cells of the lymphoreticulum were seen in numbers, as well as mast cells and plasma cells. Only a few megakaryocytes were seen.
>
> The diagnosis was moderately severe hypoplastic anemia. The patient was given 300 mg. of cortisone per day for 10 days but was discharged with little improvement.

Eight other cases of anemia associated with exposure to lindane vapors, dust, and residual spray have also been directed to the attention of the Committee. One case associated with an improperly functioning insecticide vaporizer installed in a nursery and other rooms of a home involved a 3-year-old child and a 54-year-old nursemaid. It is unestablished whether the child and the nurse were suffering from anemias induced by lindane or from common diseases frequently associated with anemia. A fatal case of aplastic anemia in which a lindane residual spray was suspected as a possible etiological agent has also been reported.

---

[1] Leland, S. J.: Some Observations on the Toxicology of Lindane, New York, Proceedings of Chemical Specialties Manufacturers Association, June 1952, p. 112.

The patient, a 58-year-old farmer, had an essentially negative history of exposure to drugs and chemicals other than spray solution of 5% lindane in petroleum solvents. The farmer had used the spray solution at one week intervals during the summer of 1952. In August, 1952, prior to seeing the physician, the patient noted purpuric spots over the body. The next day he experienced anorexia and tarry stools. The gastrointestinal hemorrhage continued, and the patient was hospitalized. Supportive therapy included transfusions of whole blood, administration of vitamin C orally, and injections of liver extract, vitamin B_{12}, methapyrilene hydrochloride (Histadyl) and cortisone; he was discharged 11 days later. He was readmitted again in five days for the reappearance of similar symptoms. Ten days later he died. The findings on physical examination and the results of laboratory tests were similar to those described in the preceding case of hypoplastic anemia, but with lower hemoglobin level and red blood cell count.

Five additional cases of injury, one fatal, attributed to exposure to a 40% mixture of technical benzene hexachloride containing an unspecified amount of the gamma isomer (lindane) have been studied by a medical clinic of a foreign university. The conclusion of the study, which is presently awaiting publication, is that benzene hexachloride causes inhibition of the development of red blood cells in the bone marrow and this may occur in the absence of demonstrable injury to the liver.

In the several instances (anemia, anuria) in which etiology was uncertain, it was obvious that opportunity for injury was present. Excessive exposure to insecticide vaporizers was caused by intimate and sustained contact with vapors from a device installed in front of an air-conditioning unit in a small food establishment and by constant contact with the vaporized lindane and its chemical breakdown products from improperly functioning units placed in living and sleeping quarters. While the clinical evidence is suggestive, it is not conclusive; however, the cumulation of cases of anemia with a common history of exposure to various forms of lindane requires that the available facts be brought to the attention of the medical profession.

These cases illustrate an increasingly common problem encountered by medical groups evaluating reports of suspected injury from new chemicals. Too often there is little concrete information, only varying degrees of ignorance about factors influencing profound changes in organs from such exposure. Since experimental animal stuies at best can provide only an indication of the type of damage which may be expected, exhaustive study and reporting of human cases outside the usual pattern of injury are imperative and should be undertaken whenever circumstances permit.

FUMIGATING DEVICES

The home use of volatilized chlorinated hydrocarbon insecticides as a "fumigating" application is being exploited as an alternate approach to the large and lucrative domestic market for inexpensive insecticide vapor and fume dispensers. Currently available fumigating applicators vary considerably in design and functional hazards. They include lindane-impregnated paper strips, recessed and perforated insecticide dispersing electric light bulbs, tins of pyrotechnic fumigant powder, and various types of vaporizing equipment for attachment to heating devices such as light bulbs or for direct insertion into electrical outlets.

The so-called fumigating type of insecticide applicator has been accepted under federal law for use in closed and temporarily unoccupied spaces where food is covered and from which birds, fish, and other susceptible species of pets have been removed. Lindane is allowed in amounts ranging from a minimum of 1 gm. per 1,000 cu. ft. to a maximum of 2 gm. per 1,500 cu. ft. of space at not oftener than two week intervals. It is recommended that use should be limited to periods ranging from one-half to four hours, depending on the apparatus used. The premises must be reaired for one-half hour before reoccupancy. The technique is based on the principle of liberating sufficient amounts of insecticide into the atmosphere of a room to exceed the saturation level. Excess insecticide precipitates out in solid state, forming a residue over exposed horizontal surfaces.

High temperature fumigating devices, which release insecticide fumes in unoccupied rooms at periodic intervals, are reasonably safe if intelligently employed, but they also have many of the same basic dangers as insecticide vaporizers. Apparatus that resemble vaporizing devices in appearance or operating principle, or that have hazards from exposed flames, or that leave accessible uncombusted insecticide are liable to accidental or intentional misuse. Variations in design and performance of various available fumigators preclude blanket description of inherent dangers other than to advise that any departure from directions on the label of the accompanying chemical exposes users to the risk of injury.

The dangers inherent in the misuse of insecticide vaporizers employed as fumigators is of sufficient magnitude to warrant a third statement by the Interdepartmental Committee on Pest Control. In a release dated March 27, 1953, the Interdepartmental Committee recommended against their use in living quarters. The statement, which is directed not only to lindane-dispensing devices but also to any vaporizer using an insecticide as a fumigating agent, was precipitated by a growing trend to circumvent existing restrictions on the use of heat-volatilizing insecticide equipment in homes. Certain types of vaporizing devices, which do not conform to earlier recommendations for construction and installation, are being promoted as so-called fumigators for home use under circumstances that leave much to be desired. Nonrecommended insecticides, alone or in combination with accepted chemicals, are being used in a manner contrary to that generally considered sound. Normal fumigation procedures are not feasible in the customary use of these "fumigating" devices; yet, anything less definitive encourages violations of accepted health practice. Since their potential harmfulness through misuse far outweighs any recognized usefulness in homes, the current restriction was invoked.

ADVERTISING AND PROMOTIONAL PRACTICES

Although existing restrictions have had a beneficial influence, it is generally recognized that they have only partially deterred many of the abuses associated with insecticide dispersing appliances. Widespread misuse arising from improper installation and continued employment of unacceptable chemicals and equipment are still prevalent. These conditions are partially caused by the inability to enforce prohibitions against certain situations, such as home use, made prior to present regulatory bans and to the difficulty of policing use in other unacceptable environments which appear to many to be similar to those where vaporizers are legally allowed. However, the flamboyant and misleading advertising of certain of the more aggressive firms marketing these dispersers is mainly responsible for their continued, widespread misapplication.

As official recommendations become more restrictive, every promotional strategem is being employed to regain general acceptance. The thinly disguised attempts to maintain dubiously acquired competitive advantages include use of nonaccepted chemicals, cleverly contrived advertising implying safety even in prohibited applications, and inferences that equipment has been endorsed or approved by recognized scientific groups such as public health organizations, universities, or agencies of the state and federal government. The most flagrant of these questionable practices is the use of nonaccepted chemicals in continuously operating vaporizing devices with claims of safety for use anywhere, including homes where even recommended chemicals are forbidden in this type of application. Methoxychlor is the principal nonapproved chemical exploited in this fashion; however, there is reasonable suspicion that at least one other compound has been so employed.

The continued extravagant promotion of certain types of insecticide vaporizers under the guise of fumigating equipment is also of great interest to those responsible for protection of the public welfare. Insecticide fumigating devices are being advertised as portable, ornamental, deodorizing (chlorophyll), disinfecting (triethylene glycol), and useful for everything but healing purposes. The absurdity of this advertising is not so much a subject of medical concern as are the claims, direct and implied, of harmlessness for uses that are in direct violation of current safety practices for volatilized chemicals. It is inevitable that such tactics will lead to misuse, which ultimately becomes the common use as demonstrated by general practice with insecticide vaporizing devices. Pressure for more laws to regulate and even ban the employment of these types of insecticide dispensers is increasing, and action is a certainty unless industry polices itself.

COUNCIL ON PHYSICAL MEDICINE AND REHABILITATION

APPARATUS ACCEPTED

The following additional products have been accepted as conforming to the rules of the Council on Physical Medicine and Rehabilitation of the American Medical Association for inclusion in Apparatus Accepted. A copy of the rules on which the Council bases its action will be sent on application.

RALPH E. DE FOREST, M.D., *Secretary.*

T. E. D. Elastic Stockings

Bauer & Black, Division of the Kendall Company, 309 W. Jackson Blvd., Chicago 6.

The T. E. D. Elastic Stockings cover the foot (except the toes) and leg up to a level just below the knee. There are three sizes: small, for a calf measuring up to 30 cm. (12 in.) in circumference; medium, for a calf measuring 30 to 38 cm. (12 to 15 in.); large, for a calf exceeding 38 cm. in circumference.

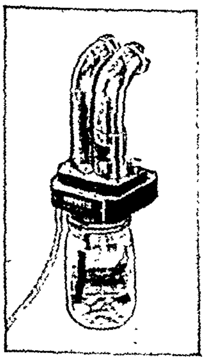
T. E. D. Elastic Stocking

The manufacturer's advertising emphasizes the use of these stockings with medical and surgical patients as a means of reducing the incidence of pulmonary embolism. Such use presupposes the possibility of maintaining the external pressure on the legs between 10 and 15 mm. of mercury. It is therefore necessary that a good fit be secured. The use of these stockings is contraindicated in the presence of ischemic vascular disease of the legs because evidence indicates that pressures as low as 10 mm. or lower reduce the blood flow through a limb in ischemic vascular disease and that such reduction may be critical in patients with incipient or actual tissue ischemia.

The Council secured evidence that the T. E. D. Elastic Stockings were well made and satisfactory when used according to instructions, with proper regard for contraindications.

Vapojette Supersaturation Attachment

Air-Shields, Inc., County Line Rd., Hatboro, Pa.



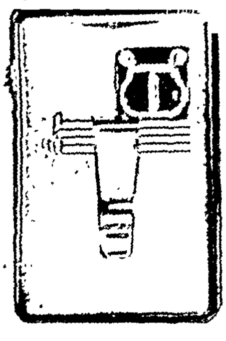
Vapojette Supersaturation Attachment

The Vapojette Supersaturation Attachment is a humidifier designed for use in connection with the Isolette Infant Incubator, which was accepted by the Council in 1949. Water is contained in a glass jar, into which an intake tube projects. The cap of the jar includes a nebulizing arrangement and bears two curved pipes that connect with two holes on the side of the transparent plastic cover or dome of the Isolette. The cap also bears a nipple for connection with the supply of oxygen or compressed air that actuates the nebulizer.

The entire unit weighs 1.1 kg. (2½ lb.). The jar contains 470 cc. when filled to the brim but is intended to hold about 320 cc. at a time. Directions state that the jar will hold enough distilled water for eight hours of use.

Beltone Mono-Pac Hearing Aids, Models Lyric and Rhapsody

Beltone Hearing Aid Company, 2900 W. 36th St., Chicago 32.



Beltone Mono-Pac Hearing Aid, Model Lyric

The Beltone Mono-Pac Hearing Aid, Model Lyric, is an electronic hearing aid employing three vacuum tubes powered by one 1.25 volt mercury-type A-battery and one 15 volt B-battery. With batteries and receiver the instrument weighs 109.6 gm. and measures 68 by 45 by 24 mm. A receiver for air conduction is provided.

The Beltone, Model Rhapsody, is similar to the Model Lyric except that a 30 volt B-battery is used. This model is intended for persons with a more severe hearing loss.

REPORT OF THE COUNCIL

The Council on Physical Medicine and Rehabilitation has authorized publication of the following article.

RALPH E. DE FOREST, M.D., *Secretary.*

POWER OUTPUT OF DIATHERMY APPARATUS

The rating in watts of a diathermy apparatus that is given on its name plate and is customarily used to designate the power output may not be a reliable indication of the ability of the apparatus to heat tissues adequately. The Council on Physical Medicine and Rehabilitation has adopted the so-called thigh test as the standard method of determining heating efficacy.* In the opinion of the Council, the temperature rise in the thigh of an average healthy adult is the most accurate way to determine the heating capacity of diathermy apparatus. In brief, acceptable diathermy equipment must raise the temperature of the thigh to 104 F in 20 minutes without injury to or burning of the skin, or subjecting the patient to intolerable pain.

The rated output of a diathermy apparatus as recorded on the name plate is usually based on results of a test on a phantom lamp, or calorimeter load. The power output revealed by the phantom load might be completely out of line with the actual ability of the apparatus to heat tissues. The reason for this misleading result lies in the so-called matching of impedances. (Impedance for alternating current is similar to resistance for direct current.) This means that the internal impedance (the combination of resistance and reactance that chokes back flow of current) of the diathermy apparatus must match the impedance of the external lamp or calorimeter load. When the two impedances are the same, the greatest output is obtained. When body tissues are heated, their impedance seldom matches the internal impedance of the diathermy apparatus. To compensate for this, the diathermy apparatus must have a reserve of energy so that the physician can be assured that ample heat can be generated in the tissues.

As one of its tests, the Council on Physical Medicine and Rehabilitation uses three lamp loads, each of different value. If satisfactory outputs are obtained on each one of the loads, the Council is reasonably assured that the apparatus will be suitable for heating tissues. When the heating efficiency is questioned, the thigh test must be used to determine the actual conditions. The Council on Physical Medicine and Rehabilitation has made extensive tests of all submitted diathermy apparatus and is convinced that those accepted have ample reserve power to treat patients.

---

* A copy of the "Minimal Requirements for Acceptable Diathermy Apparatus" may be obtained by writing the Secretary of the Council on Physical Medicine and Rehabilitation.

SURGICAL ASPECTS OF PEPTIC ULCER

In the April 25, 1953, issue of THE JOURNAL is an editorial in which surgical aspects of peptic ulcer are discussed. This editorial was based on the report of a committee of the Gastroenterological Association.[1] A major conclusion of the report was as follows: "The results following partial gastric resection alone were superior to those following vagotomy with gastroenterostomy . . . for duodenal ulcer."

In June, 1953, there appeared in *Gastroenterology* a statement on errata, corrected tables, and an important modification of interpretation of the report by the committee.[2] Its conclusion now reads: "It is now apparent that the advantage of gastric resection for duodenal ulcer over gastroenterostomy and vagotomy is shown only if there is an estimated resection of more than 70 per cent of the stomach." This statement was published in answer to a critique [3] by Dr. Keith S. Grimson and in response to questions raised by others. The critique refers only to data on surgical treatment for duodenal ulcer. The report of the committee had already carried the statement, "Vagotomy alone may be superior to gastric resection for gastrojejunal ulcer subsequent to a previous gastric resection and is attended by a lower mortality." The critique stated that, with correction of a few apparent errors in two important comparative tables, "one could then proclaim vagotomy and gastroenterostomy the preferable procedure, particularly in view of the lesser mortality risk. Of the eight criteria studied as most reflecting welfare of patients five favor vagotomy and gastroenterostomy, results of either operation seem essentially equal in two, and one favors maximum resection over resection of less than 70% of the stomach or vagotomy."

The present statement of the committee and those of the critique indicate a direction of thought different from that of the previous editorial. Incidences of unsatisfactory results of operations for duodenal ulcer [4] are given separately for patients who have had one or more previous hemorrhages and for those who had not had hemorrhages.

Among the patients who had had hemorrhages, unsatisfactory results following vagotomy and gastroenterostomy were least frequently encountered in terms of mortality (1%), dissatisfaction of the patients (6.8%), and inability to work (4.8%). Unsatisfactory results following resection of more than 70% of the stomach were least frequently found for hemorrhage after operation (4.2). After resection of less than 70% of the stomach, unsatisfactory results were less frequent for recurrence of ulcer symptoms (3.2%). The percentages favor vagotomy and gastroenterostomy in three of these five criteria, and the less extensive and more extensive resections in one each.

The committee prepared and now emphasizes a table of comparison in which the incidences of unsatisfactory results are considered from a different standpoint and are based on a composite of results according to five criteria. This new table includes the criteria of satisfaction with the operation by the patient, freedom from ulcer symptoms, ability to work, absence of evidence of recurrence on roentgenograms, and absence of postoperative hemorrhage. It includes the number of patients who are reported to have responded unfavorably according to one or more of these five criteria, and hence the percentages are not the equivalent of totals of the number with unsatisfactory results according to the individual criteria. Not included in this table are the unsatisfactory results of operative mortality, weight loss, or diarrhea and the dumping syndrome. In this table of comparison, the lowest incidence of unsatisfactory results among patients who had had hemorrhages followed resection of more than 70% of the stomach (12.2%), the next lowest followed resection of less than 70% of the stomach (20.9%), and the highest followed vagotomy and gastroenterostomy (25.0%).

Among the patients who had not had profuse hemorrhages unsatisfactory results were least frequent following vagotomy and gastroenterostomy with regard to operative mortality (1.4%), hemorrhage after operation (2.1%), and inability to work (5.5%). When the extent of the resection was more than 70%, there were fewer unsatisfactory results when judgment was based on dissatisfaction of patients (4.2), and ulcer symptoms after the operation (3.3%). Unsatisfactory results following resection of less than 70% were higher for each of the five criteria already listed. They were also highest (24.6%) by the committee summary based on a composite of results according to these five criteria, whereas for resection of more than 70% the figure was lowest (13.7%), and for vagotomy was 19.7%.

The two remaining criteria reviewed by the critique were change of weight and occurrence of side-effects, i. e., diarrhea and the dumping syndrome. Of patients whose weight was reported [1] two years after vagotomy and gastroenterostomy, 68.9% had gained weight, 16.9%

---

[4] Footnotes 1 and 2.

weighed the same, and 14.2 had lost weight. The weight of the patients who had undergone resection was not asked by the questionnaire. The comment by the committee, however, that the "incidence of weight gain at the end of two years of follow-up was higher after vagotomy plus gastroenterostomy than following vagotomy plus resection," has some bearing, as it is generally agreed that the procedure of vagotomy and gastroenterostomy is less frequently associated with loss of weight than is resection. The incidence of diarrhea among all cases was 1.9% after vagotomy and gastroenterostomy, 1.2% after less extensive resection, and 2.2% after more extensive resection. The incidence of the dumping syndrome was 3.3% after vagotomy and gastroenterostomy, 8.9% after less extensive resection, and 4.2% after more extensive resection.

It seems evident that, for the most part, resection of less than 70% of the stomach was associated with the highest incidence of unsatisfactory results. Whether results of resection of more than 70% of the stomach were equal to the results of vagotomy and gastroenterostomy is debatable. It depends upon whether the committee's summary of composite results for the five criteria used is or is not more important than the individual percentages for operative mortality, dissatisfaction, inability to work, recurrence of ulcer symptoms or hemorrhage, loss of weight, or occurrence of the two side-effects, diarrhea and the dumping syndrome. If these seven criteria are considered individually, vagotomy and gastroenterostomy was most frequently associated with the lowest incidence of unsatisfactory results and resection of more than 70% of the stomach, the next lowest.

The committee has completed an arduous task, and its members have made important modifications of their original conclusions. Their present conclusion that gastric resection for duodenal ulcer has an advantage over vagotomy and gastroenterostomy only if there is an estimated resection of more than 70% of the stomach is based on emphasis of their comparison table that is based on composite results according to five criteria. Grimson[3] and others emphasize comparison of the incidence of each unsatisfactory result of operation and believe that the use of vagotomy and gastrojejunostomy with its lesser mortality risk and its more favorable results has been demonstrated as preferable in cases of duodenal ulcer.

After 10 years of debate over which is the best operation for duodenal ulcer, it is evident that there is still no indisputable decision. Nevertheless, progress has been made. Each school of thought now recognizes the advisability of vagotomy for jejunal ulcer or of vagotomy and gastroenterostomy for a duodenal ulcer so situated that resection would be hazardous, and of resection for exsanguinating hemorrhage or for gastric ulcer. Some believe that resection and vagotomy should be combined, and this may be justified, at least for a few patients with difficult ulcer problems. Either procedure is associated with a definite incidence of unsatisfactory results and usually should be employed alone. All seem agreed, however, that no operation should be undertaken unless it is necessary.

DRAFT LEGISLATION FOR PHYSICIANS EXTENDED

On June 29, 1953, the President of the United States approved a bill (Public Law 84, 83rd Congress) that will extend until July 1, 1955, the additional liability of physicians for military service.

The American Medical Association has, since September, 1950, maintained a close and active interest in this legislation and as a consequence was able to make a valuable contribution to the final law.

In view of the extreme importance of this legislation to physicians, its specific provisions are worthy of detailed consideration. The measure as signed by the President will put into effect the following provisions:

(1) Extend the effective date of the law until July 1, 1955;

(2) Retain the same maximum ages for registration at age 50 and for liability for induction at age 51;

(3) Continue in effect the existing four priorities with the following amendments: (a) All service performed since Sept. 16, 1940, as an officer or as an enlisted man, with certain exceptions, which will be outlined later, will be credited as service. Under the original law, physicians in priorities 1 and 2 receive credit only for service performed "subsequent" to deferment or participation in a Navy V-12 or Army Specialized Training Program during World War II;

(b) The length of service required to qualify for a priority 4 classification for doctors who were deferred from service or educated at government expense during World War II is reduced from 21 to 17 months. As a result of this provision, a substantial number of doctors will be reclassified from priority 2 to priority 4. This provision does not affect the new period of service which may be required, it merely changes the definition of the priority 2 and 4 classifications.

(c) The following new periods of service will be established for men inducted or recalled to active duty, irrespective of their priority classification.

Previous Service	*New Period of Duty*
9 months or less	24 months
9 to 12 months	21 months
12 to 15 months	18 months
15 to 21 months	15 months

(d) The law would eliminate any further liability for induction or recall to active duty, except in time of war or national emergency hereafter declared by Congress, for those men in priority 4 who have had 21 months or more of service since Sept. 16, 1940.

(4) Define "active duty" and "active service" to include: (a) Full-time duty in the active service of the United States since Sept. 16, 1940, in the Army, Navy, Air Force, Marine Corps, Coast Guard or United States Public Health Service, including reserve components;

(b) Time spent in work of national importance by conscientious objectors during World War II and under the current military training and service act;

(c) Service performed before Sept. 2, 1945, in the armed forces of countries that were allies of the United States during World War II; and

(d) Service performed, as a physician or dentist, by United States citizens employed by the Panama Canal Health Department between Sept. 16, 1940, and Sept. 2, 1945.

(5) Exclude from consideration as "active duty," periods spent in a Navy V-12 or Army Specialized Training Program; in a military internship, residency or senior student program; in military service for the sole purpose of undergoing a physical examination or while engaged in active duty for training entered into after June 29, 1953;

(6) Authorize the appointment of medical officers in grades commensurate with their professional education, experience or ability. This section is intended to provide uniform treatment with respect to rank for all physicians called to active duty, irrespective of whether they had previous military service;

(7) Continue until July 1, 1955, the authority to provide the "special pay" of $100 per month for physicians in the armed forces. This section also extends the class of persons eligible for such pay to include veterinarians;

(8) Authorize the commissioning of noncitizens of the United States as officers in the armed forces;

(9) Terminate automatically, upon completion of 12 months or more of service subsequent to Sept. 9, 1950, the reserve commissions of all physicians taken into service by operation of the "Doctor-Draft" law. Upon completion of this same service, medical reservists recalled to active duty will be given an opportunity to resign their commissions. Such persons, whether registrants or reservists, shall not be liable thereafter for recall or reinduction except in time of war or national emergency hereafter declared by the Congress;

(10) Reenact the provisions of the original law which permit the deferment of those individuals who are essential to the national health, safety and interest;

(11) Authorize the national, state and local medical advisory committees to the Selective Service System, in addition to their present authority, to make recommendations with reference to the deferment of (*a*) registrants engaged in residency training, (*b*) those serving on faculties of medical and certain other schools, and (*c*) those engaged in essential laboratory and clinical research;

(12) Extend until July 1, 1955, the authority of the President to recall medical reservists to active duty involuntarily;

(13) Be retroactive in effect. Those men already in uniform who would have benefited from the new changes in the law if they had been enacted prior to their entrance into service will, upon filing and application, be eligible for release as soon as possible and in no event later than 90 days after the effective date of the Act (June 29, 1953).

In considering the over-all effect of the new law, it should be noted that the major changes involve greater recognition of prior military service. The result is that a particular registrant, by being able to take advantage of the various new provisions, may either (*a*) become exempt from liability for service, (*b*) be placed in a priority less vulnerable to immediate call, (*c*) be subject to a reduced term of service, or (*d*) effect a severance of military status within 90 days upon application or after the completion of his period of service by being either discharged or permitted to resign.

In comparing the new law with the testimony presented by the American Medical Association before the Armed Services Committees of the House of Representatives and the Senate, it is interesting to note that many recommendations were accepted and others were modified or rejected.

As examples of the latter, it will be noted that the Association recommended that the liability for registration and call-up of veteran physicians in priority 4, as well as the involuntary recall of medical reservists in this category, be terminated as of July 1, 1953. The law, as enacted, excuses from further liability those registrants and reservists in priority 4 with 21 months or more of service since Sept. 16, 1940. This law amounts to substantial acceptance of the Association's recommendation, since between 85 and 90% of the physicians in priority 4 have 21 months or more of service.

In an effort to afford a greater measure of equity in priority 2 cases, the Association recommended that the second period of duty be limited to 12 months for a physician who had 12 or more months of previous service. In addition, it was suggested that all accrued or terminal leave as well as travel time be included in computing total service. The law does not allow credit for accrued leave, and instead of the prescribed period of one year's service, a staggered period of service was established (see item 3(*c*) above).

It was also the belief of the Association that the reserve commissions of physicians called into service by operation of the law should not be vacated automatically upon completion of required service. Instead, it was felt that physicians should be given the option of retaining or resigning their commissions and that reserve officers in the Navy and Marine Corps with service in World War II should be permitted to resign their commissions immediately if they wished to do so. The recommendations of the Association in this regard were not accepted.

Perhaps the most significant suggestion made by the Association was that any extension of the law be limited to one year and that an earnest effort be made by the Congress and the armed forces to devise alternative methods for securing needed medical officer personnel. It is sincerely hoped that the action of the Congress in extending the law for two years is not an indication of an attitude of acceptance of the draft law as a continuing device for procuring physicians for the armed services.

If members of the Congress and representatives of the armed forces are sincere in their reference to the "Doctor-Draft" law as "temporary" and "discriminatory" legislation, they will take immediate steps to discontinue it at the earliest possible time. A step in this direction would be the immediate implementation of the following alternative suggestions that were made by the Association in its testimony: (1) Increased utilization of civilian contract physicians in performing the medical duties of the armed services; (2) Investigation of ways of increasing the attractiveness of service in the military and naval medical corps and the development of a more efficient program for medical officers and allied health personnel procurement; (3) Improved utilization of medical personnel and curtailment in their assignment to nonprofessional duties; and (4) A reduction in the amount of medical care provided by physicians in uniform to dependents of service personnel.

WARNING ON INSECTICIDE VAPORIZERS

Elsewhere in The Journal (page 1232) is a report of the Committee on Pesticides on the health problems of lindane insecticide vaporizer and fumigator devices. The Committee's present report supplements its earlier warnings on vaporizer hazards by providing additional laboratory and clinical evidence of the risks attendant to improper use of these devices and the highly toxic material that they dispense. Recommendations against the use of insecticide vaporizers in homes, sleeping quarters, or where food can become contaminated were made nearly two years ago. In spite of the warnings and their subsequent extension to other areas of use and related operations, this type of insecticide volatilizing equipment continues to be advertised and promoted as safe and harmless for use in homes, hospitals, nurseries, and similar unacceptable locations. The current report of the Committee on Pesticides questions the wisdom and ethics of these promotional practices in view of the cumulating evidence of the dangers of insecticide vaporizers and fumigators in such environments.

THE PRESIDENT'S PAGE

A MONTHLY MESSAGE

In reading about the current military developments in Korea and other parts of the world where our troops are employed, I cannot help but recall some of my own reactions while in uniform. I am sure that all of us who have been in service have at some time during our tour of military duty experienced the feeling that we were forgotten by our friends and colleagues at home. Inasmuch as this feeling is frequently occasioned by lack of communication, I would like to devote the President's Page this month to a discussion of things that the American Medical Association has done and is doing with respect to military medical affairs. I believe these activities, which are conducted primarily by the Council on National Emergency Medical Service, will demonstrate clearly that physicians in the armed forces have not been forgotten or neglected by their national professional society.

One of the primary interests of the Association during the past several years has been the "Doctor-Draft" law. Since the passage of the legislation in September, 1950, the Association has attempted to (1) facilitate and increase the efficiency of the administration of the law; (2) effect a timely and orderly system of recall and rotation of medical reservists; (3) prevent a repetition of the medical overstaffing that occurred in certain areas during World War II; and (4) curtail the utilization of medical personnel on nonprofessional assignments and in the treatment of military dependents.

On June 29, 1953, the President signed Public Law 84, 83rd Congress, which extended a revised version of the law until July 1, 1955. The detailed explanation of that measure, which is contained in this issue of THE JOURNAL, indicates the extent of the interest and active participation that the Association has maintained in this matter. During the past six months alone, the Council on National Emergency Medical Service has received hundreds of letters, phone calls, and personal visits from physicians in service or from those about to be called under the act. These inquiries have been handled promptly, and they have been utilized in effecting many equitable changes in the new law.

There are many less publicized but equally important activities of the Association that are conducted for the benefit of physicians in service. At present the Council on National Emergency Medical Service is engaged in two such projects. The first of these, started approximately 10 months ago, is a continuing survey of physicians released from active military service. To date, a total of 4,404 questionnaires have been sent to such physicians, and 3,040, or 70%, have been filled out and returned. Results of this survey will be used as the basis for a series of conferences with the Assistant Secretary of Defense for Health Affairs and the Surgeons General to further improve the utilization of medical personnel by the armed forces and to formulate a more effective voluntary officer procurement program. The second project is to acquaint physicians being released from service with existing civilian medical opportunities. This program, inaugurated with the cooperation of the Department of Defense and the Selective Service System, is endorsed by the state medical societies and the chairmen of state volunteer medical advisory committees to the Selective Service System.

Names of physicians to be released from service, together with other information, are supplied the Council by the three Surgeons General. The Council then writes each physician, inquiring as to his present plans, his medical qualifications, and the state in which he prefers to train or practice. The names of physicians who want additional information are sent to the chairman of the appropriate volunteer medical advisory committee and, through the Council on Medical Service, to the Physician Placement Services of the state medical societies.

From July 28, 1952, to June 30, 1953, letters were sent to 4,251 individual physicians. Of this number, 809 requested further information. The response to date indicates that a real service to physicians, state medical societies, and state volunteer medical advisory committees has resulted.

Space does not permit a full discussion of the many other activities of the Council. One deals with the "special pay" of $100 per month for doctors in the armed forces, the authority for which was extended until July 1, 1955. I have suggested, and the Council now has under consideration, the publication of a monthly newsletter for keeping physicians in the armed forces fully informed as to activities of the Association in their behalf and current developments in the various fields in which they are interested.

I know that I speak for the Council on National Emergency Medical Service and for all of the officers of the Association in pledging continued active interest in medical military affairs and in the immediate and postservice problems of the physicians in uniform. If there are ways in which you believe we can be more effective in fulfilling our obligations in this regard, let me assure you that your suggestions will be most welcome.

EDWARD J. MCCORMICK, M.D., Toledo, Ohio

ORGANIZATION SECTION

COMMITTEE ON LEGISLATION

At its meeting on May 30, 1953, the Committee on Legislation took action on 39 legislative measures introduced in the 83rd Congress, recommending either approval or disapproval. All of the recommendations were approved by the Board of Trustees on June 4, 1953. Following is a brief résumé of these bills grouped according to subject, together with the position adopted by the Association in each instance.

MEMBERS OF THE ARMED SERVICES AND THEIR DEPENDENTS

S. 1495 (identical bill: H. R. 4642)

Introduced by Mr. Murray of Montana and referred to the Senate Committee on Labor and Public Welfare.

Digest of Bills.—The bills would authorize the furnishing of medical, nursing and hospital maternity and infant care to the wives and children of members of the armed forces below the rank of warrant officer. The program would be administered by the Children's Bureau, through grants to states which have approved state plans providing such care. The program would be effective until the present national emergency is declared ended.

Association Position.—The Association **actively opposes** these bills on the ground that there is no demonstrated need for such a program.

VETERANS AND VETERANS ADMINISTRATION

S. 1068

Introduced by Mr. Griswold of Nebraska and Mr. Ives of New York and referred to the Committee on Labor and Public Welfare.

Digest of Bill.—The bill would amend Veterans Regulation Numbered 6 (a), as amended, to authorize the Administrator of Veterans' Affairs to supply hospital care and medical treatment to veterans who are citizens of the United States visiting or residing abroad for disabilities incurred in service.

Association Position.—The Association **supports** the principle of providing care for veterans with service-connected disabilities, but opposes this bill, as drafted, because it is too vague and may possibly authorize the construction of Veterans Administration hospitals overseas.

H. R. 4155

Introduced by Mr. Elliott of Alabama and referred to the Committee on Veterans' Affairs.

Digest of Bill.—The bill would amend Veterans Regulation Numbered 1 (a), as amended, to establish a presumption of service connection for chronic and tropical diseases "becoming manifest" within two years after separation from active service.

Association Position.—The Association **actively opposes** this bill because it is too general and does not define the terms "chronic" and "tropical diseases." In addition, the bill represents another effort to further liberalize existing Veterans Administration regulations regarding the presumption of service connection. The continuation of such a policy of liberalization will not only result in a distortion of the theory on which compensation benefits are based but will also result in the extension of hospitalization and medical care benefits to veterans with disabilities that are in actuality not service connected, regardless of their ability to pay for such care from private sources.

H. R. 4601

Introduced by Mr. Teague of Texas and referred to the House of Representatives Committee on Veterans' Affairs.

Digest of Bill.—The bill would amend section 6 of Public No. 2, 73rd Congress, as amended, by restating existing medical and hospital benefits for veterans with service-connected disabilities and by redefining such benefits for veterans with non-service-connected disabilities.

The bill would eliminate the present provision of the law, which provides: "The statement under oath of the applicant on such form as may be prescribed by the Administrator of Veterans' Affairs shall be accepted as sufficient evidence of inability to defray necessary expenses" and would, instead, give the administrator the authority to determine these veterans with non-service-connected disabilities who are unable to pay for care. The requirement of inability to pay would not apply to veterans in need of "extensive hospital treatment for chronic or long-term non-service-connected ailments which . . . will incapacitate them from earning a living for an indefinite period of time."

In addition, the Administrator of Veterans Affairs would be authorized to collect from a veteran with non-service-connected disabilities for necessary hospital care at the established rate if the veteran agrees to pay or if the administrator finds the veteran is able to pay.

Association Position.—The Association **actively opposes** this bill because, if enacted, the present status of medical care for veterans with non-service-connected disabilities would be further confused, and the program would be expanded rather than curtailed.

EDUCATION

H. R. 3850

Introduced by Mrs. Bolton of Ohio and referred to the House of Representatives Committee on Interstate and Foreign Commerce.

Digest of Bill.—The bill would provide for (1) a limited three year program with appropriations of 5 million dollars for the first year, 10 million dollars for the second year, and 15 million dollars for the third year, with additional amounts for practical nursing education grants; (2) administration of state programs by state boards of nurse examiners—state plans to improve and expand nurse training facilities would be in accordance with criteria set forth in the bill; (3) the allocation of federal funds to each state in proportion to the number of newly-enrolled nurse trainees, and (4) scholarships awarded by the state boards of nurse examiners on the basis of ability and financial need of applicants.

Association Position.—The Association **opposes** this bill because the Association feels that legislative proposals providing federal financial assistance must be free of the strings of federal control common to this type of bill. Alternative recommendations were presented in detail by Dr. Walter B. Martin in his appearance relative to H. R. 910, 82nd Congress, before the Committee on Interstate and Foreign Commerce of the House of Representatives on Sept. 13, 1951.

TAX RELIEF

S. 1154 (identical bills: H. R. 3583 and H. R. 3585)

Introduced by Mr. Ives of New York and Mr. Flanders of Vermont and referred to the Senate Committee on Finance.

Digest of Bills.—The bills would amend section 23 of the Internal Revenue Code (relating to allowable deductions from gross income) so as to permit deductions by individuals and by corporations of amounts paid as subscription charges to cooperating prepayment health service plans as defined in Title VII of the Public Health Act. These amendments would be applicable with respect to taxable years beginning after Dec. 31, 1949.

Association Position.—The Association **opposes** these bills because they favor a particular type of insurance plan, i. e., those eligible for certain state loans for health facilities.

H. R. 3375 (identical or similar bills: H. R. 3434, H. R. 3779, H. R. 3911, and H. R. 4450)

Introduced by Mr. Matthews of Florida and referred to the Committee on Ways and Means.

Digest of Bills.—The bills would authorize the deduction of medical and dental expenses, not compensated for by insurance or otherwise, for the medical care of the taxpayer, his spouse, or his dependents.

Note: Under present law medical expenses are deductible only after the adjusted gross income has been determined and such expenses exceed a minimum amount (5% of adjusted gross income) and are not in excess of a fixed maximum ($2,500 on an individual return; $5,000 for a husband and wife, jointly).

Association Position.—The association **actively approves** the bills in principle since they would afford individual relief in cases of extremely high medical expenses and would also be an incentive to buy voluntary health insurance.

H. R. 4393

Introduced by Mr. Davis of Georgia and referred to the House of Representatives Committee on Ways and Means.

Digest of Bill.—The bill would amend the Internal Revenue Code to allow persons engaged in teaching school or in any other profession to deduct, as trade or business expenses, and in determining adjusted gross income, ordinary and reasonable educational expenses paid or incurred for the purpose of (1) carrying on his profession, (2) making himself better qualified for his profession, or (3) increasing his remuneration from his profession. The amendments would be applicable with respect to taxable years beginning after Dec. 31, 1952.

Association Position.—The Association **actively supports** this bill in line with its long-established position that physicians should be permitted to deduct postgraduate educational expenses for income tax purposes.

SOCIAL SECURITY AND DISABILITY INSURANCE

H. R. 3487 (similar bill: H. R. 3608)

Introduced by Mr. Lane of Massachusetts and referred to House of Representatives Committee on Ways and Means.

Digest of Bills.—The bills would amend title II of the Social Security Act (relating to Old Age and Survivors Insurance) by extending coverage to additional employees and to certain self-employed groups. In referring to self-employed groups, the bill would give credit for income derived "by an individual from any trade or business carried on by such individual" or "from any trade or business carried on by a partnership of which he is a member."

Although physicians are not mentioned specifically, they would be included in the group of self-employed covered by the bills.

Association Position.—The Association **actively opposes** these bills insofar as they refer to physicians. This action is in accord with the action of the House of Delegates taken in June, 1949.

H. R. 3554 (similar bill: H. R. 3777)

Introduced by Mr. Zablocki of Wisconsin and referred to the Committee on Ways and Means.

Digest of Bill.—The bill would provide disability insurance benefits for permanently and totally disabled persons who are unable to engage in any substantially gainful activity by reason of a medically determinable physical or mental impairment or blindness.

The bill would also provide benefits for wives and children of the totally disabled and would define retirement age as 65 for men and 60 for women.

Association Position.—The Association **actively opposes** the bills, thus reiterating the past opposition of the Association to amendments to the Social Security Act providing for permanent and total disability and cash sickness benefits and a broad rehabilitative program for Social Security beneficiaries.

It is the belief of the Association that the initiation of a federal disability benefit program would represent a major step toward the wholesale nationalization of medical care and the socialization of the practice of medicine. The provisions of these bills would establish an inferior type of physician-patient relationship, which would undoubtedly result in a deterioration of medical care.

In addition it is felt that legislation of this type should not be considered until the study of the entire Social Security System now being made by Congressman Carl T. Curtis is complete.

H. R. 4160

Introduced by Mr. Keane of New Jersey and referred to the Committee on Ways and Means.

Digest of Bill.—The bill would provide for a waiver of Social Security tax payments during periods of permanent and total disability.

Disability is defined as "inability to engage in any substantially gainful activity by reason of any medically determinable physical or mental impairment which can be expected to be permanent, or blindness." Benefits (waiver of premiums) would not be allowed for a period of disability less than six months.

The eventual larger Old Age and Survivors Insurance pensions would come from the Social Security Trust Fund, maintained by payroll taxes from employer and employee. The trust fund also would be used for two additional purposes: (1) to pay governmental or private agencies or organizations for services in determining the existence, continuation and termination of disability; (2) to relieve the states of any cost of rehabilitation if, within the first six months, a state cooperating with the federal government under the Vocational Rehabilitation Act certifies that the individual appears to be rehabilitable to gainful employment.

The Federal Security Administrator could not require anyone claiming benefits to undergo a physical examination to establish disability; however, in lieu of such examination the applicant would have to furnish proof of disability satisfactory to the Administrator or forego benefits. Also, the bill contains this provision: "Nothing in this title shall be construed as authorizing the Administrator or any other officer or employee of the United States to interfere in any way with the practice of medicine or with relationships between practitioners of medicine and their patients, or to exercise any supervision or control over the administration or operation of any hospital."

Association Position.—The Association **actively opposes** the bill for the following reasons: 1. The Association favors the adoption of a formula for computing Old Age and Survivors Insurance benefits based on a wage earner's best five or ten years. Such a formula would obviate the necessity for special consideration in cases involving permanent and total disability. 2. The proposals contained in the bill have not been thoroughly explored. 3. The provisions of the bill, although administrable by state agencies, would require the establishment of over-all standards and regulations by the Federal Security Agency. 4. The intervention by the federal government in this phase of medical activity would be a further interference in the field of private medical care.

H. R. 4676

Introduced by Mr. Ford of Michigan and referred to the House of Representatives Committee on Ways and Means.

Digest of Bill.—The bill would amend various sections of the Social Security Act to redefine the terms "old-age assistance" and "aid to the blind" and "aid to the permanently and totally disabled" to include medical care in behalf of or any type of remedial care recognized under state law for beneficiaries under such three programs if the individuals concerned are patients in non-public institutions. Patients in public medical institutions other than tuberculosis or mental would be eligible.

Association Position.—The Association **actively opposes** this bill on the grounds: (1) that the health and medical welfare of the individual is his personal responsibility, and that financial aid should be rendered to the individual only when he is unable to provide it himself; and (2) that financial aid should be rendered by philanthropic, local, and state agencies first and that federal aid should be sought only when funds are not available from these sources.

COMPULSORY HEALTH "INSURANCE" AND FEDERAL SUBSIDIZATION OF PRIVATE PLANS

S. 1153 (identical bills: H. R. 3582, H. R. 3586 and H. R. 4128)

Introduced by Mr. Ives of New York and Mr. Flanders of Vermont and referred to the Senate Committee on Labor and Public Welfare.

Digest of Bills.—These are omnibus bills which propose a variety of legislative changes in the role of the federal government in medicine. The legislation, if enacted, would be known as the "National Health Act, 1953," and would provide for the following items:

(a) *Federal Aid to Voluntary Health Service Plans.*—This part of the bill would authorize federal assistance to voluntary nonprofit prepayment health service plans. Funds would be paid to a designated state agency by the Surgeon General of the U. S. Public Health Service for administration, provided the state had a plan previously approved by the Surgeon General.

(b) *Authorize Federal Payroll Deductions for Health Insurance Premiums.*—This section would authorize the deduction of premiums for health insurance from the salaries of employees of the federal government or members of the Armed Forces.

(c) *Loans to Health Service Plans for Building and Equipping Personal Health Service Centers.*—This section of the bill would authorize the appropriation of a 10 million dollar loan fund to be used by the Surgeon General to make loans to assist in the establishment and equipping of personal health service centers.

(d) *Federal Aid to Medical and Nursing Schools.*—This section would provide federal financial assistance to medical and nursing schools for construction and toward the cost of establishing, maintaining, and enlarging their staffs and of operating and maintaining their facilities, including the acquisition of equipment. Payments would be based upon the number of old and new students enrolled.

(e) *Health Study and Planning.*—This section would authorize the creation of a permanent commission to study the nature and extent of the health needs of the nation and to formulate effective long-range health plans.

(f) *Federal Aid to Local Public Health Units.*—The purpose of this section is to develop, extend and improve basic state and local public health organizations. The section would authorize state grants to develop and maintain public health services, including the establishment of new local public health units, the training of personnel for state and local public health work, and provision of measures for the prevention, treatment, and control of disease. The section would also authorize the Surgeon General of the U. S. Public Health Service to provide demonstrations and to train personnel for state and local public health work.

Association Position.—The Association **actively opposes** these bills since they would federalize certain health activities that can and should be planned for and operated on a local level and because the bills are incompatible with the sound philosophies concerning the rendition, distribution, and financing of medical care enunciated by the Association.

H. R. 4593

Introduced by Mr. Hagen of Minnesota and referred to the Committee on Interstate and Foreign Commerce.

Digest of Bill.—The bill would authorize federal assistance to voluntary, nonprofit associations offering prepaid health service programs to secure facilities and equipment through long term interest bearing loans. The bill would make available federal funds that could be borrowed at 2% interest for the purpose of operating health insurance plans, such funds to be used only for the construction of clinics and diagnostic and treatment centers.

The Surgeon General of the U. S. Public Health Service, with the advice of a National Health Services Facilities Council, would formulate standards for the making of loans, the determining of eligibility of organizations, the amount of loans, amortization, and determining priority for making loans.

The bill defines "health services" as meaning "services such as are provided by physicians and dentists and similar professional groups, members of which are licensed under state laws, laboratory and x-ray services and other services related thereto."

Association Position.—The Association **actively opposes** the bill since it would federalize certain health activities which can and should be planned for and operated on a local level.

MISCELLANEOUS

S. 1436

Introduced by Mr. Griswold of Nebraska and referred to the Committee on Government Operations.

Digest of Bill.—This bill would establish a federal Board of Hospitalization to be composed of the Attorney General of the United States, the secretaries of Defense and the Interior, the Administrator of Veterans' Affairs, the Federal Security Agency and the General Services Administration, and the Director of the Bureau of the Budget. The Administrator of Veterans' Affairs would act as chairman of the board.

The board would attempt to coordinate the construction and utilization of hospital facilities by the federal government to prevent overlapping and duplication of services and overbuilding of facilities.

Association Position.—The Association **approves** the principle of the establishment of a federal Board of Hospitalization but **disapproves** the present bill, and recommends that any board that is established be composed of the Secretary of the Interior, the Director of the Bureau of the Budget, and a representative of the Department of Defense and that the number of civilian members be at least equal to the number of government representatives. Government officials in charge of medical programs should serve in an advisory capacity only.

S. 1584

Introduced by Mr. Murray of Montana and referred to the Senate Committee on Labor and Public Welfare.

Digest of Bill.—The bill would charge the Public Health Service with responsibility for: (*a*) disseminating pertinent facts concerning leprosy, including information regarding the latest important medicines and methods for treating the disease; (*b*) advising and cooperating with other government and private agencies in this field; (*c*) studying and investigating conditions, problems and needs in this field; and (*d*) providing treatment in existing federal and state facilities or in new facilities or paying for necessary private medical care.

In addition, the bill would authorize the establishment of a National Advisory Council on Leprosy, which would advise the Surgeon General of the Public Health Service. Programs would be authorized for rehabilitation and reemployment of leprosy patients, for financial assistance for patients and their dependents, and for compensation for disability. The bill would also authorize the expenditure of federal funds for research under the direction of the Surgeon General of the Public Health Service to discover causes and cures for the disease.

Association Position.—The Association **actively opposes** this bill because there are already existing agencies for such a program under the Surgeon General of the U. S. Public Health Service. In addition, the need for the type of expansion proposed by the bill has not been demonstrated.

H. R. 3204

Introduced by Mr. Yates of Illinois and referred to the House of Representatives Committee on Interstate and Foreign Commerce.

Digest of Bill.—The bill would authorize the U. S. Public Health Service to admit to its hospitals persons committed by state courts who are beneficiaries of the service or narcotic addicts. Such care would be subject to the availability of accommodations and within the discretion of the Surgeon General.

Association Position.—The Association approves the bill because of the existing shortage of proper facilities for the persons covered by the bill.

H. R. 3473 (similar bill: H. R. 4262)

Introduced by Mr. Doyle of California and referred to the Committee on Education and Labor.

Digest of Bills.—The bills propose to establish an independent federal agency to be known as the Federal Agency for Handicapped, to provide various types of rehabilitative services to persons physically or mentally handicapped. The agency would absorb the functions of the Office of Vocational Rehabilitation; the Division of the Physically Handicapped in the Bureau of Labor Statistics; the functions of the Library of Congress in furnishing aid for the blind; and the functions of the Federal Security Agency with respect to the Vocational Rehabilitation Act and state grants for aid to the blind. The new agency also would coordinate all other rehabilitative measures for the benefit of handicapped persons, administered by other agencies of the government.

The following specific programs, financed in whole or in part by the federal government and subject to federal approval and control, would be authorized: (*a*) loans to persons or corporations engaged in the rehabilitation of handicapped persons; (*b*) grants to states for payment of monthly benefits to needy handicapped persons unsuitable for rehabilitation; (*c*) grants to local school boards and nonprofit educational groups providing special services to handicapped persons; (*d*) establishment of a revolving loan fund to refinance state educational rehabilitative plans; (*e*) special federal and state recruitment and employment programs; (*f*) public safety programs; (*g*) special programs for severely handicapped persons, including establishment of workshops; (*h*) the establishment of rehabilitation centers; and (*i*) the establishment of a Federal Second Injury Act.

Association Position.—The Association opposes these bills pending the report of the new commission on federal-state relationships.

H. R. 3551 (similar bill: H. R. 3604)

Introduced by Mrs. Sullivan of Missouri and referred to the Committee on Interstate and Foreign Commerce.

Digest of Bills.—The bills would amend Section 704 of the Federal Food, Drug and Cosmetic Act by restoring authority in the Food and Drug Administration to inspect factories without first making a request and obtaining permission. The exhibiting of appropriate credentials by an authorized officer or employee would authorize the entering and inspecting of "any factory, warehouse, or establishment in which food, drugs, devices, or cosmetics are manufactured, processed, packed or held" or to enter "any vehicle used to transport" such products.

Association Position.—The Association approves the principle of the bills, provided that proper safeguards are included to protect the physician-pharmacist-patient relationship. It believes that the inspection privilege should not be extended to confidential business and professional regards that have no specific bearing on the enforcement of the Food, Drug and Cosmetic Act.

H. R. 4145

Introduced by Mr. Bailey of West Virginia and referred to the House of Representatives Committee on Education and Labor.

Digest of Bill.—The bill would authorize the expenditure of federal funds to states on a matching basis for industrial safety programs. The amounts payable to the various states would be based on population, the number of wage earners, special industrial hazards, area of protection, the cost of state administration, and the financial needs of the states.

The Secretary of Labor would be charged with the responsibility for administering the program and for passing the acceptability of state industrial safety plans.

Association Position.—The Association opposes the bill to await the findings of the commission being established to study federal-state relationships.

H. R. 4456

Introduced by Mr. Heller of New York and referred to the House of Representatives Committee on Interstate and Foreign Commerce.

Digest of Bill.—The bill would authorize federal financial assistance to "certain large cities in the United States" with a population in excess of 100,000 for the establishment and maintenance of uniform centralized ambulance control systems. The sum of 2 million dollars would be authorized for this purpose to be administered by the "Federal Security Administration" through designated municipal agencies.

Association Position.—The Association opposes this bill as unnecessary and an encroachment of the federal government in private and local government affairs.

H. J. Res. 72 (identical bill: H. J. Res. 174)

Introduced by Mr. Ray of New York and referred to the House of Representatives Committee on Interstate and Foreign Commerce.

Digest of Resolutions.—These resolutions would authorize the Surgeon General of the Public Health Service, the Secretary of Agriculture, and the Secretary of the Interior to conduct research, investigation, experiments, and demonstrations into the causes, effects, and means of prevention and control of air pollution. Appropriations would be provided for the next five years for this work. The Surgeon General, the Secretary of Agriculture, and the Secretary of the Interior could seek the assistance of other federal, state, and local as well as public and private agencies and bodies concerned with the problem. A joint annual progress report would be submitted by the Surgeon General and the Secretary of the Interior to the Congress.

Association Position.—The Association approves these resolutions because the subject is new and unknown in the field of medicine and research is necessary.

H. Res. 146

Introduced by Mr. Dollinger of New York and referred to the House of Representatives Committee on Rules.

Digest of Resolution.—The resolution would authorize the creation of a select committee, composed of seven members of the House of Representatives, to be appointed by the Speaker to conduct a full and complete investigation and study of air pollution in the United States. The study would cover the causes, relative seriousness by area, effects, and methods of eliminating air pollution.

The resolution calls for a report to the Congress and would give the committee the power to hold hearings and to subpoena witnesses, documents and records.

Association Position.—The Association approves this bill because the subject is new and unknown in the field of medicine and research is necessary.

H. J. Res. 230

Introduced by Mr. Hebert of Louisiana and referred to the Committee on the Judiciary.

Digest of Resolution.—The resolution proposes an amendment to the Constitution of the United States which would limit the present scope of treaties and executive agreements. Specifically the proposed amendment would: (*a*) render void any treaty or executive agreement which denies or abridges any right enumerated in the Constitution; (*b*) outlaw any treaty authorizing any foreign power or international organization to adjudicate constitutional rights of United States citizens or any domestic issue; and (*c*) require domestic legislation to permit a treaty to become effective as internal law in the United States.

To become operative the proposed Constitutional amendment, if adopted by Congress, must be ratified by the legislatures of three-fourths of the states within seven years from the date of its submission.

Association Position.—The Association actively approves this resolution. This is in accord with the position adopted by the House of Delegates in December, 1952.

THE SCIENTIFIC EXHIBIT, ST. LOUIS CLINICAL MEETING, DEC. 1-4, 1953

Arrangements are in progress for the Scientific Exhibit at the Clinical Meeting of the American Medical Association in St. Louis, Dec. 1-4, 1953. The Chairman of the Subcommittee on Scientific Exhibit is O. P. J. Falk, M.D., 18 S. Kingshighway, St. Louis 8. The Scientific Exhibit will be correlated as far as possible with the various sections chosen for the meeting, and the subchairmen from St. Louis will act in an advisory capacity for the various section groups as follows:

Medicine	Ralph A. Kinsella, M.D.
Surgery	Carl A. Moyer, M.D.
Pediatrics	Peter Danis, M.D.
Obstetrics and Gynecology	Robert Crossen, M.D.
Tuberculosis	Paul Murphy, M.D.
Cardiovascular Disease	Arthur E. Strauss, M.D.
Arthritis	R. O. Muether, M.D.
Dermatology	G. V. Stryker, M.D.
Gastrointestinal Diseases	Jos. W. Larimore, M.D.
Neuropsychiatry	Edwin F. Gildea, M.D.

Application blanks for space in the Scientific Exhibit are now available and may be obtained from any of the physicians mentioned above or from the Director, Scientific Exhibit, American Medical Association, 535 N. Dearborn St., Chicago 10. Applications will close on Sept. 15.

NEW SECRETARY FOR COUNCIL ON MEDICAL EDUCATION AND HOSPITALS

Dr. Edward L. Turner, dean of the School of Medicine and chairman of the Division of Health Sciences of the University of Washington in Seattle since 1945, has been appointed Secretary and administrative officer of the Council on Medical Education and Hospitals. Dr. Turner will assume the secretaryship on Oct. 1.

Dr. Turner received the B.S. degree in 1922 and the M.S. degree in 1923 from the University of Chicago. He received his M.D. from the University of Pennsylvania in 1928. After serving on the staff of Albert Merritt Billings Hospital, University of Chicago, Dr. Turner was appointed to the faculty of the American University of Beirut, where from 1933 to 1936 he was professor of medicine. In 1936, Dr. Turner was appointed professor of medicine at Meharry Medical College, and in 1938 he also became president of the college and continued in that capacity until 1944. During this period he supervised the reorganization of the schools of medicine, dentistry, nursing, medical laboratory technology, and dental hygiene as well as the George W. Hubbard Teaching Hospital of the college.

In 1944 Dr. Turner entered private practice in Bradford, Pa., but a year later was called to Seattle as dean and professor of medicine to organize the new medical school of the University of Washington.

Dr. Turner has written numerous articles in the fields of physiology, internal medicine, tropical medicine, and medical education. He is a diplomate of the American Board of Internal Medicine, is a former vice-president of the Association of American Medical Colleges, and is currently a member of the association's executive council. He is a member of the Washington State Medical Association, a fellow of the American College of Physicians, a member of the Association of American Physicians, and a member of the National Advisory Heart Council. Dr. Turner succeeds Dr. Donald G. Anderson, Secretary of the Council since 1947, who has been appointed Dean of the University of Rochester School of Medicine and Dentistry.

Dr. Edward H. Leveroos, who has been Associate Secretary of the Council on Medical Education and Hospitals since 1948, has been appointed to the newly created position of Director, Division of Hospitals and Graduate Education, of the Council on Medical Education and Hospitals. In this new position, Dr. Leveroos will be in direct charge of the Council's program of approving hospitals for internship and residency training and of the activities of the Council's staff in the program of the Joint Commission on the Accreditation of Hospitals.

Dr. Leveroos graduated from the Superior State Teachers College in 1931 and received his M.D. from the University of Minnesota in 1940. After interning at the Minneapolis General Hospital, Dr. Leveroos served in the Air Force until 1946, at which time he held the rank of Lieutenant Colonel. Dr. Leveroos received the degree of Master of Hospital Administration from Northwestern University in 1947. He was clinical director of the Veterans Administration Hospital, Hines, Ill., at the time he joined the Council's staff in 1947.

FEDERAL MEDICAL LEGISLATION

Broadening Social Security

The present Social Security System would be broadly revised by a bill, S. 2260, introduced by Senators Lehman (D., N. Y.), Murray (D., Mont.), Jackson (D., Wash.), Humphrey (D., Minn.), Kennedy (D., Mass.), Douglas (D., Ill.), Green (D., R. I.), Morse (Ind., Ore.), Pastore (D., R. I.), Neely (D., W. Va.), and Magnuson (D., Wash.). A number of changes are proposed, chief of which are (1) extension of coverage to an estimated 8 million persons not now covered, including members of the armed forces, farm owners, farm workers, additional household workers, ministers, certain groups of public employees, and some professional groups, including lawyers, veterinarians, accountants, architects, funeral directors, and engineers, but not physicians or dentists; (2) increase of that portion of wages subject to tax from $3,600 to $6,000; (3) increase of monthly dollar benefits of various types to a maximum of $162 for one individual who has been covered 40 years and has a $500 a month average wage (see Congressional Record 99:7984 [July 1] 1953); (4) increase of from $75 to $100 in the amount a retired person under the age of 75 could earn in a month without suspension of his benefit payment; (5) provision of benefits equal to primary retirement benefits for permanently and totally disabled persons. (During periods of such disability, benefit status would be frozen so that, if the person already is or later becomes eligible for retirement benefits, the benefit level would not be reduced by wages lost because of disability.) To be eligible for permanent and total disability insurance the individual must have contributed for 5 of the 10 years preceding his disability and for a year and a half in the three and one-fourth years immediately preceding his disability. Disabled persons are required to submit to examination and reexamination from time to time under regulations of the Secretary of the Department of Health, Education, and Welfare. The Secretary could stop benefit payments if a disabled person refused rehabilitation, evaluation, and training. State rehabilitation agencies would furnish rehabilitation services and be reimbursed for the full cost from the social security trust fund. The Secretary is authorized to secure the cooperation of appropriate federal, state, or other political agencies and of private medical, dental, hospital, nursing, health, educational, and social welfare groups in carrying out the disability benefit section); and (6) establishment of a cash sickness insurance, with benefits limited to 26 weeks, for persons temporarily disabled.

This bill was referred to the Committee on Finance. It is identical with H. R. 6034 (Dingell, D., Mich.), H. R. 6035 (Bolling, D., Mo.), H. R. 6036 (Roosevelt, D., N. Y.), H. R. 6041 (Celler, D., N. Y.), H. R. 6042 (Dodd, D., Conn.), H. R. 6043 (Eberharter, D., Pa.), H. R. 6044 (Elliott, D., Ala.), H. R. 6045 (Howell, D., N. J.), H. R. 6046 (Rhodes, D., Pa.), H. R. 6056 (Shelley, D., Calif.), and H. R. 6072 (Holifield, D., Calif.), all of which were referred to the Committee on Ways and Means.

Transportation of Fireworks

Senator Bridges (R., N. H.) in S. 2245 proposes to prohibit the transportation of fireworks into states that prohibit their sale. This bill is identical with H. R. 116 (Church), previously reported, recently amended, and reported favorably to the House by the Committee on the Judiciary. It was referred to the Committee on the Judiciary.

The summary of federal legislation was prepared by the Washington Office of the American Medical Association and the summary of state legislation by the Bureau of Legal Medicine and Legislation.

Medical Care for Veterans

Congressman Teague (D., Texas) in H. R. 6015 would amend the present law on hospitalization and medical care of veterans to make the Administrator rather than the veteran determine whether the veteran is able to pay for non-service-connected disability or illness care. Hospitalization and treatment in non-service-connected cases would still depend on the availability of beds. A preference order would be established for admission of veterans with non-service-connected illness, preference being given "after emergency cases . . . to those in need of extensive hospital treatment for chronic or long-term non-service-connected ailments to the extent that facilities available for cases in these categories will permit. In determining whether the veteran is unable to defray the necessary expenses of hospitalization, the Administrator shall take into account, along with other factors, the fact that a veteran has an insurance contract, on a prepaid or reimbursement basis, covering all or part of needed hospital care, or is otherwise covered for all or part of necessary hospital care." This was referred to the Veterans' Affairs Committee.

Loans to College Students

Congressman Boland (D., Mass.) in H. R. 6079 proposes to establish a federal scholarship revolving loan fund to which each state would contribute an amount not to exceed 10% of the loans advanced to that state's students during the preceding year. Loans would be made at the rate of not more than $1,000 a year for college-grade studies and $1,500 a year for postcollege-grade studies over a period of four years. States would furnish lists of eligible borrowers to the U. S. Commissioner of Education, but advances could be made only to students accepted by an educational institution. This measure was referred to the Committee on Labor and Education.

STATE MEDICAL LEGISLATION

California

Bills Enacted.—H. R. 167, was adopted June 10, 1953. It directs the Interim Committee on Public Health to study and analyze all facts relating to the whole field of public health including hospital districts, operation of ambulances, fluoridation of water, **conduct of massage establishments, coroners and revision of the coroner system**, etc. H. R. 215, was adopted June 9, 1953. It would memorialize Congress to take the necessary steps to insure that sufficient funds be appropriated to the appropriate agencies so that adequate medical care and treatment is accorded to ill and disabled veterans and further to take necessary steps to insure that **no more veterans hospitals are closed** until such time as there is a conclusive showing that a surplus of beds for veterans who need care exists. A. 1175, has become ch. 1045 of the laws of 1953. It amends the medical practice act relating to **reciprocity applicants** who complete their course of training in a school which has been approved by the board at the time the reciprocity application is filed, if the school was approved by the board in 1949 or prior to that year and if the applicant meets certain other requirements. A. 2239, has become ch. 913 of the laws of 1953. It amends the law relating to witnesses in narcotic cases by providing that **no witness may refuse to testify** to any fact or produce any paper concerning which he is examined in such proceeding for the reason that his testimony or the production of the paper may tend to incriminate him. S. R. 143, was adopted June 10, 1953. It directs the interim committee on the education and rehabilitation of handicapped children and adults to study and analyze the existing state policies pertaining to the **education and rehabilitation of all types of physically and mentally handicapped persons**, with particular reference to the financial, administrative, professional, and legal problems involved in providing special education and rehabilitation for such persons, including, but not limited to, the study, analysis, and investigation of all matters pertaining to this resolution. S. R. 174, was adopted June 7, 1953. It memorializes the Congress of the United States to take necessary steps to insure that sufficient funds are appropriated to the appropriate agencies so that adequate medical care and treatment is accorded to ill and disabled veterans and to take necessary steps to insure that **no more veterans hospitals are closed** until such time as there is a conclusive showing that a surplus of beds for veterans who need care exists. S. 602, has become ch. 1051, of the laws of 1953. It amends the law relating to vocational nursing by, among other things, setting forth facts constituting **unprofessional conduct** which would authorize the suspension or revocation of a nurse's license. It also authorizes the board to suspend the license of a person who is so mentally ill as to be unable to carry on with safety to the public the practice authorized by the license. S. 606, has become ch. 1053 of the laws of 1953. It amends the law relating to nursing by, among other things, defining the term **"unprofessional conduct"** and by authorizing the board to suspend the license of a licentiate who is so mentally ill as to be unable to carry on with safety to the public the practice authorized by the license.

Hawaii

Bill Enacted.—S. 567 relating to the reporting of gunshot wounds was previously reported as having been approved June 16, 1953. The bill was not approved. It died in the House.

Maine

Bill Enacted.—H. 1197, was approved May 8, 1953. It authorizes the governor to appoint a **state committee on aging** to study the problems, both of the state itself and its people, which arise with the tremendous increase in numbers and from changed attitudes towards our older citizens.

Massachusetts

Bill Enacted.—H. 2756, has become ch. 63 of the resolves of 1953. It resolves that the commission established in 1951 to study the problem of **a state medical and dental school** under the jurisdiction of the University of Massachusetts also will consider the development of an adequate program of higher education.

Nebraska

Bill Enacted.—L. R. 29, was adopted June 4, 1953. It directs the Nebraska legislative council to study the medical, social, and economic problems pertaining to **the aged and mentally ill.**

New Hampshire

Bill Enacted.—H. 430 has become ch. 228 of the laws of 1953. It provides for the creation of a **council on mental health** to advise and consult upon common problems in the field of mental health.

Ohio

Bill Introduced.—S. 294, proposes regulations for the examination and treatment of **mentally abnormal sex deviates** by qualified psychiatrists.

Bill Enacted.—H. 494, was approved June 5, 1953. It authorizes the **executive-secretary** of the county child welfare fund, upon the advice of one or more reputable practicing physicians, **to consent to medical, dental and surgical care**, including surgery and the administration of anesthetics, innoculations, and immunizations, or other care as appears necessary for any child who is a ward of such board.

Oklahoma

Bills Enacted.—H. 585, was approved June 15, 1953. It is a **university hospital psychiatry and neurology service act** to provide the citizens of Oklahoma with a diagnostic and remedial psychiatry and neurology service, to provide the school of medicine of the University of Oklahoma with a means of furnishing professional education and research in psychiatry and neurology, and to provide for the administration and use of the facilities, located in the university hospital, for this purpose. H. 953, was approved June 20, 1953. It makes it unlawful for any optometrist, physician or other person making eye examinations to receive or accept any **rebate, kickback, reward, or premium** from any optical company or any other person or to knowingly allow or permit any person engaged in or interested in the sale of such optical goods to solicit business for any person licensed under the provisions of the medical practice act or the optometry practice act. S. 241, was approved June 12, 1953. It provides appropriations for the Oklahoma commission for crippled children and also provides that whenever the terms "physician" and medical care and hospitalization are used in the act the same shall include **osteopathic practitioners** and the services of osteopathic practitioners and hospitals within the scope of their practice as defined by state law.

Pennsylvania

Bills Introduced.—H. 1536, proposes the establishment of **a division of alcohol studies and rehabilitation** to study the problems of alcoholism, treat, and rehabilitate persons addicted to excessive use of alcoholic beverages and promote preventive and educational programs designed to eliminate alcoholism. S. 706, proposes to provide **scholarships for the medical education** of qualified residents in the commonwealth. Persons accepting such scholarships shall enter into an agreement with the commonwealth whereby they shall agree to serve in any state institution designated by the secretary of welfare as an intern or resident for a period of not less than four years after graduation from medical school.

Bills Enacted.—H. 38, was approved June 19, 1953. It amends the **penalty provisions of the narcotic act** by authorizing imprisonment up to 30 years for second and subsequent offenses and by providing that in the case of second or subsequent offenses the offender shall not be entitled to a suspended sentence or to parole. H. 779, was approved June 19, 1953. It amends the law relating to chiropractic by, among other things, authorizing the board to license by reciprocity individuals from other states and provinces of the Dominion of Canada if the standards of licensing in such states and provinces are substantially the same as those provided in Pennsylvania and if similar privileges are accorded persons licensed in this commonwealth and if the applicants hold valid licenses and if the applicable rules and regulations prescribed by the board are followed.

Wisconsin

Bills Enacted.—S. 162, has become ch. 325 of the laws of 1953. It amends the medical practice act by providing for an **osteopathic member** of the state board of medical examiners. S. 360, has become ch. 330 of the laws of 1953. It is a **hospital regulation and approval act** requiring hospitals to obtain the approval of the state board of health before they engage in business.

MEDICAL NEWS

ARKANSAS

Barlow Memorial Fund.—Friends of the late Dr. Brian E. Barlow have established the Brian E. Barlow Memorial Fund, which will be used to purchase equipment at St. Mary's Hospital in Dermott.

Society News.—The Arkansas Obstetrical and Gynecological Society, which was formed April 20 in conjunction with the Arkansas State Medical Society, elected Dr. Eugene T. Ellison, Texarkana, president, Dr. Willis E. Brown, Little Rock, president-elect, Dr. Robert W. Ross, Little Rock, secretary-treasurer, and Drs. Hoyt L. Choate, Little Rock, and Haynes G. Jackson, Hot Springs National Park, members of the executive committee.

"Dr. Norris Day."—Dr. Rutial O. Norris, Tuckerman, a past president of the Jackson County Medical Society, was recently honored by his community, which celebrated "Dr. Norris Day" with a public reception. Dr. Norris, who has practiced in Tuckerman for 40 years, has been president of the National Eclectic Medical Association and treasurer of the Arkansas Eclectic Medical Association. He is a past president of the Tuckerman Service Club.

CALIFORNIA

Postgraduate Courses.—The University of California at Los Angeles School of Medicine and University Extension, in cooperation with the San Diego County Medical Society, offers postgraduate instruction in therapeutics, office gynecology, and peripheral vascular diseases in a program to be given from 9 a. m. to 5 p. m., Aug. 12, 19, and 26 in building 153, U. S. Naval Hospital, San Diego. Additional information may be secured from Dr. Thomas H. Sternberg, University of California Medical Extension, Los Angeles 24.

Dr. Geiger Honored.—The president of the Republic of Brazil, His Excellency Getulio Vargas, has conferred on Dr. Jacob C. Geiger, health officer, Oakland, the highest degree of the decoration La Cruz del Sud (the Southern Cross), with the following citation: "For distinguished and valuable services rendered to the Government of Brazil and its people in the fields of public health, medicine, and science." His native state, Louisiana, also honored Dr. Geiger by giving him a commission as a colonel on Governor Kennon's staff and making him an honorary senator of the Louisiana State Senate.

ILLINOIS

Warning Against Wood Ticks.—Dr. Roland R. Cross, state public health director, Springfield, has issued a warning to outdoor recreation seekers concerning the dangers of being bitten by wood ticks, some of which transmit Rocky Mountain spotted fever. Three cases, one terminating fatally, have been reported in Illinois since the last week in May.

Dr. Ole Nelson Retires.—Dr. Ole C. Nelson, medical superintendent of Cook County Hospital, Chicago, has retired at the age of 71 after 42 years of service. Dr. Nelson, who was familiarly known as "Mr. County Hospital," was honored at a staff luncheon at the hospital as well as at a reception and a tea at Karl A. Meyer Hall, the new interns' residence. On behalf of the Cook County commissioners, officials, physicians, nurses, and other associates honoring Dr. Nelson, Dr. Karl A. Meyer, surgical director of Cook County institutions, presented Dr. Nelson with an automobile.

Chicago

Cardiac Funds to Researchers.—Checks totaling $91,800 were recently presented by the Chicago Heart Association to 13 Chicago research scientists. The largest awards ($10,000 each) went to Drs. Albert Dorfman, George E. Wakerlin, Louis N. Katz, and Earl P. Benditt.

"Golden Apples" Awarded.—The Raymond B. Allen instructorship awards, keys in the form of golden apples, have been presented by students at the University of Illinois College of Medicine. Designed to honor excellency in individual instructorship, they were awarded to Dr. Heyworth N. Sanford, clinical professor of pediatrics; Dr. Frank B. Kelly, clinical professor of medicine; Dr. Norman B. Roberg, clinical assistant professor of medicine; Theodore R. Sherrod, Ph.D., assistant professor of pharmacology; and Faith LaVelle, Ph.D., instructor in anatomy.

IOWA

Dr. Tharp Honored.—Nearly 400 persons attended a dinner in the Monroe High School gymnasium to honor Dr. Herbert M. Tharp, who has served the community for 25 years. The program, patterned after the television program, "This Is Your Life," brought together persons who had played an important role in Dr. Tharp's career, including a surgical nurse from the Chicago clinic where he took his internship, several of the women who served in his office, his first patient in Monroe, and his first and last babies. The Monroe Commercial Club presented a scroll inscribed "A Salute to Dr. H. M. Tharp, whose 25 years of long, diligent and faithful service to the community as physician, surgeon and benefactor have earned for him this recognition."

LOUISIANA

Society News.—At the annual meeting the New Orleans Graduate Medical Assembly elected Dr. Andrew V. Friedrichs, president, Dr. Woodard D. Beacham, president-elect, Drs. Howard R. Mahorner, Ambrose H. Storck, and Theodore L. L. Soniat, vice-presidents, Dr. Maurice E. St. Martin, secretary, and Dr. Jules Myron Davidson, treasurer. The 17th annual meeting will be held March 8-11, 1954, at the Municipal Auditorium.

Portraits Presented to Tulane.—Oil portraits of the late Dr. Isadore Dyer, former dean, the late Dr. Wilbur C. Smith, professor of gross anatomy, and Dr. Edward L. King, professor emeritus of obstetrics, were recently presented to Tulane University of Louisiana School of Medicine, New Orleans. During the presentation ceremonies Dr. Lucien A. LeDoux, New Orleans, paid tribute to Dr. Dyer as the founder of the home in Carville for patients with leprosy in 1894. Dr. Dyer, who was editor of the *New Orleans Medical and Surgical Journal* and of the *American Journal of Tropical Diseases and Preventive Medicine,* was twice Vice-President of the American Medical Association, and was one of the founders and fifth president of the Southern Medical Association. Dr. Isadore Dyer is head of the division of obstetrics at the school, and Dr. John Lewis Dyer, instructor in medicine.

MASSACHUSETTS

Dr. Kirkwood Appointed Health Commissioner.—Dr. Samuel B. Kirkwood, Brookline, has been appointed to a five year term as commissioner of public health of the Commonwealth of Massachusetts to replace Dr. Vlado A. Getting, health commissioner for the past 10 years, who has been appointed professor of public health practice at the University of Michigan School of Public Health in Ann Arbor and consultant to

---

Physicians are invited to send to this department items of news of general interest, for example, those relating to society activities, new hospitals, education and public health. Programs should be received at least three weeks before the date of meeting.

the Detroit Department of Health. Dr. Kirkwood, who in 1934-1935 was epidemiologist for the division of tuberculosis of the Massachusetts Department of Health, in 1939 joined the faculty of the Harvard University School of Public Health, where since 1946 he has been assistant professor of maternal health.

University News.—Dr. Joseph S. Barr, clinical professor of orthopedic surgery, and Dr. Fredrick J. Stare, professor of nutrition, Harvard Medical School, Boston, were among 13 medical scientists who recently spent seven weeks in Indonesia as an international team recruited by the World Health Organization to exchange scientific information with Indonesian colleagues.——The Boston University School of Medicine announces that Dr. Martin J. English, after 22 years of service, has retired from his positions as professor and head of the department of pediatrics and chief of the pediatric service at the Boston City Hospital. Dr. Eli Friedman has succeeded Dr. English as chief of the pediatric service at the Boston City Hospital, and Dr. David M. Greeley, assistant dean at the Boston University School of Medicine, has been appointed acting head of the department of pediatrics and director of pediatric teaching at the Boston City Hospital.

NEW JERSEY

Society News.—The Radiological Society of New Jersey recently elected Dr. Vincent M. Whelan, Red Bank, president, Dr. Nicholas G. Demy, Plainfield, vice-president, Dr. Salomon Silvera, Jersey City, secretary, and Dr. Carye-Belle Henle, Newark, treasurer.

Orthopedic Contest.—The New Jersey Orthopaedic Society announces its annual contest (prize $100) for the best original contribution in the field of orthopedic surgery submitted by an intern or resident of a New Jersey hospital. The project, which may deal with any aspects of orthopedics, must be completed during the internship or residency, or within six months thereafter. Papers should be submitted to the secretary, Dr. William Kruger, 31 Lincoln Park, Newark, on or before Jan. 15, 1954.

Dr. Rake Honored.—Dr. Geoffrey William Rake, recently elected mayor of Millstone, and coordinator of the office of scientific affairs of E. R. Squibb and Sons Division, Mathieson Chemical Corporation, has been named a member of the board of directors of the American Institute for the Tropics and chairman of its committee on medicine and public health. Dr. Rake was affiliated with the Johns Hopkins Hospital, Baltimore, the Rockefeller Institute, New York, and the University of Toronto in Canada before he became head of the microbiology division of the Squibb Institute for Medical Research in 1937. Dr. Rake will attend the International Congress of Tropical Medicine and Malaria in Istanbul, Turkey, and will be U. S. delegate to the International Congress of Microbiology, which will be held in Rome, Italy, in September.

NEW YORK

State Radiological Society Organized.—Under the aegis and during the annual meeting of the Medical Society of the State of New York in Buffalo, the Radiological Society of New York State was organized to federate into one group the radiologists of the state, in order "to advance the knowledge of radiology not only for diagnostic but for treatment purposes and to advance the use of the new forms of radiant energy and to promote the betterment of public health." A tentative constitution and bylaws were adopted and the following temporary officers elected: Dr. W. James MacFarland, Hornell, president; Dr. Percival A. Robin, Hempstead, vice-president; and Dr. Mario C. Gian, Buffalo, secretary and treasurer.

Dr. Hilleboe Honored.—Dr. Herman E. Hilleboe, Albany, New York state commissioner of health, was awarded an honorary doctor of science degree by Rochester University at its 103rd annual commencement. In making the presentation, Dr. George H. Whipple, dean, University of Rochester School of Medicine, cited Dr. Hilleboe as "physician, investigator, administrator of rare vision and exceptional capacity for accomplishment." Dr. Hilleboe, who previously served as epidemiologist in the state department of health, Minnesota, and in the National Institutes of Health, U. S. Public Health Service, Washington, D. C., was promoted to assistant surgeon general in 1944 and moved to New York State in 1947.

New York City

Dr. Swift Receives Award in Rheumatism.—The American Rheumatism Association recently bestowed on Dr. Homer F. Swift, member emeritus of the Rockfeller Institute since 1946, its distinguished service award for research in rheumatic fever. This is the second time the award has been made since the association was formed 23 years ago.

Personal.—At the annual dinner of the Surgical Supply Division of the United Jewish Appeal, Dr. Marcus D. Kogel, commissioner of hospitals, was awarded a special citation for "his leadership in, and dedicated service to, the progress of health-giving industry and the betterment of the city, and for outstanding service for the progress of our community."

University News.—Dr. Richard C. deBodo, associate professor of pharmacology, New York University College of Medicine, has been appointed to the rank of full professor. Dr. deBodo formerly studied under a Rockefeller Fellowship in London with the University College and the National Institute for Medical Research, while holding teaching appointments as an associate professor of pharmacology from 1920 through 1929 with the University of Pécs in his native Hungary. He has been on the faculty of the College of Medicine since 1929 and served as acting chairman of the department of pharmacology for six months in 1952.

New Medical Director for Equitable Life.—Dr. Norvin C. Kiefer, director of the Health and Special Weapons Defense Division of the Federal Civil Defense Administration since 1951, has been appointed chief medical director of the Equitable Life Assurance Society of the United States, effective Aug. 1. Dr. Kiefer was commissioned in the regular corps of the U. S. Public Health Service in 1945, transferred to the Office of the Surgeon General of the U. S. Public Health Service in 1948 and placed in charge of a new program of Health Emergency Planning, and a year later made director of the Medical Services Division of the National Security Resources Board.

OHIO

Memorial Wading Pool.—A children's wading pool was recently dedicated at the War Memorial Park, Toronto, as a memorial to Dr. Horace D. McCulloch, who practiced in that town for 40 years. Dr. McCulloch founded and was for many years director of the city health department. Contributions for the pool, which was a project of his fellow members of the Toronto Kiwanis Club, were made by various local church, social, fraternal, and industrial organizations.

President McCormick Honored.—In recognition of the election of Dr. Edward J. McCormick, Toledo, to the Presidency of the American Medical Association, the House of Representatives of the 100th Ohio General Assembly recently adopted a resolution "in tribute and respect to an outstanding Ohioan who through the forces of industry, ability, and leadership has attained one of the highest honors his profession can bestow upon him." The resolution pointed out that Dr. McCormick, a past president of the Ohio State Medical Association, has served in numerous other official capacities from the local to the national levels; that in 1949 he was a member of the medical mission invited by General Douglas MacArthur to make a survey of Japan's health needs; and that in the following year he went to Geneva as a U. S. delegate to the third assembly of the United Nation's World Health Organization. Dr. McCormick was recently honored also by Xavier University, Cincinnati, which bestowed on him the honorary degree of doctor of laws during its commencement exercises, at which he delivered the principal address.

PENNSYLVANIA

Commission on Geriatrics.—The Medical Society of the State of Pennsylvania has appointed the following commission on geriatrics: Drs. B. Franklin Rosenberry, Palmerton, chairman; Joseph T. Freeman, Philadelphia, chairman of the Commission on Geriatrics of the Philadelphia County Medical Society; Andrew B. Fuller, Pittsburgh; William J. Daw, Wilkes-Barre; Harry M. Klinger, Danville; George W. Chamberlin, Reading; George B. Rush, Aliquippa; Roy W. Goshorn, Allentown; and Edward F. Corson, Philadelphia. The commission, expressing its desire to cooperate with state agencies having to do with problems of the aged, has offered its services in the medical field.

Pittsburgh

Society News.—The Pittsburgh Roentgen Society has elected Dr. Edwin J. Euphrat, president, Dr. Peter M. Feltwell, vice-president, Dr. Donald H. Rice, secretary, and Dr. Newton Hornick, treasurer.

Grant for Investigation of Alaskan Health Problems.—Dr. Thomas Parran, dean of the Pittsburgh Graduate School of Public Health, will direct a study of health problems in Alaska under the sponsorship of (1) the U. S. Department of the Interior, which has made a $90,000 grant, (2) the government of Alaska, and (3) the several federal departments concerned with health problems there. A team of public health specialists from the university, consisting of Dr. Parran, Dr. James A. Crabtree, professor of public health practice, Antonio Ciocco, Sc.D., professor of biostatistics, and Walter J. McNerney, assistant professor of hospital administration, will conduct a survey this summer and another during the summer of 1954. The project will attempt to learn more about the health status of Alaska's native population and to develop both immediate and long-range plans for improved health services for both the native and non-native population. It is scheduled to be completed by Dec. 31, 1954. The work is to "include but not be limited to" the following fields: (1) collection and analysis of available data on the general health and hospital problems of the native and contiguous white population, with special data on tuberculosis, pneumonia, maternal and child health, mental health, and crippled children's services; (2) description and analysis of existing programs, facilities and services, federal, territorial, and private, available to meet these health problems, and the legal and administrative arrangements under which they operate; (3) preparation of immediate and long-range recommendations on (*a*) medical programs, hospitals, and other facilities, and services required to meet both general and specific health problems and (*b*) the organizational, administrative, and financial arrangements for federal, territorial, and nongovernmental responsibility and participation.

SOUTH CAROLINA

Cancer Grant.—According to the Columbia Medical Society of Richland County, S. C., Inc., the Richland County Legislative Delegation has sponsored an appropriation of $2,500 to be used by the Bob Seibels Jr., M.D., Memorial Laboratory, Columbia, in detection of cervical cancer among indigent patients. To qualify for this free service, the physician need merely give the name and address of the patient and state that he is making no charge for his services to her. Physicians desiring to make use of this cytodiagnostic method can obtain the blank forms and containers by calling the laboratory (2-2139).

TEXAS

University News.—The University of Texas Alumni Association has elected Dr. Thomas M. Oliver, Waco, president; Dr. Howard O. Smith, Marlin, president-elect; Dr. Kleberg Eckhardt, Corpus Christi, vice-president; and Miss Mildred Robertson, Galveston, secretary-treasurer.

Courses at Poliomyelitis Respirator Center.—Physical therapy procedures in the comprehensive treatment of the cardiorespiratory poliomyelitis patient are considered in relation to the physiological, psychological, and sociologic implications in the courses being given at the Southwestern Poliomyelitis Respirator Center, Jefferson Davis Hospital, Houston. Courses of four weeks will start on Aug. 3, Aug. 31, Sept. 28, and Oct. 26. For additional information write to Laura K. Smith, Supervisor of Education.

VIRGINIA

Dr. Nicholls Retires.—Dr. James B. Nicholls, superintendent and medical director of Catawba Sanatorium, recently retired after 36 years of service. Dr. Cecil C. Smith, who was formerly affiliated with a VA Tuberculosis Center in Mississippi, has been appointed as Dr. Nicholls's successor.

Dr. Martin Honored.—Dr. Walter B. Martin, Norfolk, President-Elect of the American Medical Association, was recently honored at a Portsmouth Naval Hospital dinner, presided over by Rear Adm. Sterling S. Cook (MC), U. S. N., new medical director of the hospital. Among the speakers who paid tribute to Dr. Martin were Dr. James L. Hamner, Mannboro, president, Medical Society of Virginia; Dr. Edward E. Haddock, mayor of Richmond; Dr. James M. Hutcheson, Richmond, member of the A. M. A. House of Representatives; Rear Adm. I. N. Kiland, U. S. N. commandant of the Fifth Naval District; and Dr. Clayton W. Eley, president of the Norfolk County Medical Society. The banquet was attended by 175 federal service physicians and a group of physicians from Norfolk, Portsmouth, Richmond, Charlottesville, and Suffolk.

WEST VIRGINIA

Hospital News.—Ground was broken at Beckley July 4 for a new 200 bed hospital, the first of 10 to be built for the beneficiaries of the United Mine Workers of America Welfare and Retirement Fund, of which John L. Lewis is chairman of the board of trustees. Among those participating in the ceremonies were Governor William C. Marland, formerly a coal miner, Mayor George B. Chambers, Beckley, Dr. John T. Morrison, Washington, D. C., assistant executive medical officer of the fund and president of the Memorial Hospital Associations, Dr. Frederick D. Mott, Washington, D. C., medical administrator of the associations, and Dr. Deane F. Brooke, Beckley, United Mine Workers area medical administrator. Four operating and two delivery rooms will be constructed in the hospital and an outpatient clinic in a separate building. X-ray, laboratory, and other medical service departments will serve both clinic and hospital patients. Buildings will be constructed to provide a limited number of apartments for nurses and technicians and to house the school of practical nursing and students' dormitory.

Personal.—The following physicians were recently elected to honorary life membership in the West Virginia State Medical Association: David F. Pauley, Jeffery, Charles W. Lemon, Lewisburg, Desausseur G. Preston, Lewisburg, Benjamin A. Smith, South Charleston, Ira Connolly, Parkersburg, and Joseph U. Kimble and Clare F. Shafer, both of Grafton.——Dr. Henry M. Brown, Belle, plant physician for E. I. DuPont de Nemours Company, who retired May 1 after 33 years' service, accepted appointment as county health commissioner of Clinton County, Ohio. His new offices are located at Wilmington, Ohio.——Dr. Leonard E. Neal, Clarksburg, has been elected president of the West Virginia University Alumni Association.——Former students of Gideon Stanhope Dodds, Ph.D., of Morgantown, who taught histology and embryology at the West Virginia University School of Medicine from 1918 to 1951, have arranged to have his portrait painted for the lounge of the new school of medicine.——Dr. Henry C. Huntley, Charleston, director of disease control, state department of health, since May 1, 1950, has resigned to accept appointment as medical consultant in the civil defense program, with offices in West Chester, Pa., where his address is FCSC, Region 2, High and Market Streets.——Dr. William R. Laird, founder and chief surgeon of the Laird Memorial Hospital in Montgomery, was awarded the honorary degree of doctor of humane letters by West Virginia Wesleyan College in Buckhannon at the 63rd annual commencement.

GENERAL

Muscular Dystrophy Grants.—The Muscular Dystrophy Associations of America, Inc., during the first half of 1953 have financially supported research programs in 25 institutions in the United States and one in France, expending a total of $280,802 for 27 projects. The largest grant, $61,495, went to New York Hospital, Cornell University Medical College, New York, for an investigation into the pathogenesis of progressive muscular dystrophy by Dr. Ade T. Milhorat.

Essays on Psychosomatic Medicine Invited.—The American Psychosomatic Society, which will hold its annual meeting at the Jung Hotel in New Orleans, March 27-28, 1954, invites submission of titles and abstracts of papers for consideration for the program. The time allotted for the reading of each paper will be 25 minutes. The committee is interested in investigations in the theory and practice of psychosomatic medicine as applied to adults and children in all the medical specialties, and in contributions in psychophysiology and ecology. Abstracts should be submitted in quadruplicate, before Dec. 1, to Dr. George L. Engel, chairman, program committee, 551 Madison Ave., New York 22.

Director of Tuberculosis Education Appointed.—Dr. Julius Lane Wilson, Philadelphia, director of clinics and professor of medicine in the Henry Phipps Institute for the Study, Treatment and Prevention of Tuberculosis, University of Pennsylvania, and chief consultant to the Bureau of Tuberculosis Control, Pennsylvania Department of Health, has been named to the newly created post of director of medical education, medical section, National Tuberculosis Association. He will continue to devote part of his time to his work in Philadelphia. Dr. Wilson was formerly visiting physician of Charity Hospital of Louisiana and head of the section on chest diseases at the Ochsner Clinic, New Orleans. He has taught at Yale University School of Medicine, New Haven, Conn., and at Tulane University of Louisiana School of Medicine, New Orleans.

Society News.—At the annual meeting at the Lake Placid Club, Essex County, N. Y., the American Gynecological Society elected Dr. Richard W. TeLinde, Baltimore, president, Drs. Karl H. Martzloff, Portland, Ore., and Arthur H. Bill, Cleveland, vice-presidents, Dr. John I. Brewer, Chicago, secretary, and Dr. Robert A. Kimbrough Jr., Philadelphia, treasurer. The society will hold its 1954 annual meeting at the Homestead, Hot Springs, Va., May 20-22.——The following physicians participated in a panel entitled "Working Together for Healthier Mothers and Children" at the first annual meeting of the National Nursing Association in Cleveland, June 22: Dr. Benjamin M. Kagan, chairman, department of pediatrics, Michael Reese Hospital, Chicago; Dr. Nicholson J. Eastman, obstetrician-in-chief, Johns Hopkins Hospital, Baltimore; and Dr. Helen M. Wallace, director, bureau for handicapped children, New York City Department of Health.

Prize Essay Contest in Dermatology.—The American Dermatological Association will award cash prizes ($500, $300, and $200) for the best essays submitted for original work, not previously published, relative to some fundamental aspect of dermatology or syphilology. Competition is open to scientists generally, not necessarily to physicians. Manuscripts, typed in English with double spacing and ample margins as for publication, together with illustrations, charts, and tables, all of which must be in triplicate, are to be submitted not later than Dec. 1 to Dr. J. Lamar Callaway, Secretary, American Dermatological Association, Duke Hospital, Durham, N. C. Results will be announced before Jan. 1, 1954. The candidate winning first prize may be invited to present his paper before the annual meeting of the American Dermatological Association (April 13-17, 1954, at the Greenbrier Hotel, White Sulphur Springs, W. Va.), with expenses paid in addition to the $500 prize.

Mississippi Valley Contest Winners.—The Mississippi Valley Medical Society announces the following winners of the 1953 essay contest: Dr. Arthur H. Keeney, clinical instructor in ophthalmology, University of Louisville School of Medicine, has won first prize "for the best unpublished essay on a subject of practical and applicable value to the general practitioner of medicine." Dr. Keeney will present his essay "Grass Roots in the Prevention of Blindness" at the annual meeting of the society in Springfield, Ill., Sept. 24, and will receive a cash award, a gold medal, and a certificate of award. Second prize was awarded to Dr. Louis T. Palumbo, chief, surgical service, VA Center, Des Moines, Iowa, for his paper "Physiological Changes of the Upper Gastrointestinal Tract Following Combined Upper Gastrectomy and Vagus Resection." Dr. A. Henry Clagett Jr., VA Hospital, Wilmington, Del. ("Some Common Complications of Myocardial Infarction") and Dr. Walter M. Block, Cedar Rapids, Iowa ("Infant Feeding with Homogenized Milk") tied for third prize.

Prevalence of Poliomyelitis.—According to the National Office of Vital Statistics, the following number of reported cases of poliomyelitis occurred in the United States, its territories, and possessions in the weeks ended as indicated:

Skinner Memorial Lecture.—Friends of the late Dr. Edward Holman Skinner, Kansas City, Mo., are assembling a memorial fund, the earnings of which and parts of the principal, if necessary, will be used to defray the expenses of a physician to deliver the opening lecture each year at the fall conference of the Kansas City Southwest Clinical Society, which Dr. Skinner founded. The trust agreement provides for suitable use of any surplus funds by contributions to the medical libraries of the Jackson County Medical Society and of the University of Kansas Medical Center. No campaign or general solicitation will be made, but funds in any amount from friends of Dr. Skinner will be gladly received and only the name of the donor recorded in the book of donors. Checks should be sent to the Edward Holman Skinner Memorial Fund, % Traders National Bank, 1111 Grand Ave., Kansas City 6, Mo. The first Edward Holman Skinner Memorial Lecture, "Carcinoma of the Lung," will be delivered by Dr. Alton Oschner, New Orleans, on Sept. 28 as the opening feature of the 31st annual fall clinical conference of the Kansas City Southwest Clinical Society.

March of Dime Grants.—The National Foundation for Infantile Paralysis recently announced approval of new March of Dimes awards amounting to $2,283,384 to 21 universities, medical schools, hospitals, and organizations for the support of poliomyelitis research and professional education programs: $762,380 for research seeking methods for preventing the disease and developing improved methods of treatment and $1,521,004 for programs in professional education. In the latter classification, $334,108 was awarded for pilot studies "to integrate the concept and skills of complete medical rehabilitation" in the curricula of George Washington University School of Medicine, Washington, D. C., the University of Pennsylvania School of Medicine, Philadelphia, New York University College of Medicine, and Cornell University Medical College, New York. According to Mr. Basil O'Conor, president of the foundation, since 1938 the March of Dimes organization has provided 50 million dollars for studies of medical care problems, aid to professional education, and the support of polio research; an additional 148 million dollars was spent for treatment for patients requiring financial assistance.

Radiological Conference in Denver.—The Midsummer Radiological Conference of the Rocky Mountain Radiological Society will be held in the Lincoln Room, Hotel Shirley-Savoy, Denver, Aug. 20-22, under the presidency of Dr. H. Milton Berg, Bismarck, N. D. Dr. Edward J. McCormick, Toledo, Ohio, President of the American Medical Association, will be the speaker at an informal banquet Friday, 7:30 p. m., at which Dr. Kenneth D. A. Allen, Denver, will act as toastmaster. Other guest speakers and their first presentations include:

David G. Pugh, Rochester, Minn., Myelofibrosis and Myelosclerosis.
Merrill C. Sosman, Boston, Roentgen Studies in Patients with Mitral Disease.
Sven Roland Kjellberg, Stockholm, Sweden, Value of Heart Volume Determinations.
D. B. McGrigor, London, England, Reminiscences of 44 Years of Radiology in the British Army Medical Service.
Frederic E. Templeton, Seattle, Muscular Contraction Patterns in Certain Esophageal Conditions.
Vincent W. Archer, Charlottesville, Va., Protection of Radiological Personnel During Diagnostic Procedures.
John P. Caffey, New York, Pulmonary Cysts of Early Infancy: Their Natural Regression.

Thursday Dr. Berg and Dr. Lumir R. Safarik, president of the Denver Medical Society, will preside at the joint meeting with the Denver Medical Society, 8 p. m., following an informal guest speakers' dinner at 6 p. m. Dr. Sosman will serve as moderator for a film reading session with Drs. Archer, Caffey, Kjellberg, Pugh, and Templeton as collaborators.

DEATHS IN OTHER COUNTRIES

Prof. Dr. Friedrich Franz Friedmann, professor of tuberculosis at Berlin University, died at Monte Carlo, Feb. 19, at the age of 77.

MEETINGS

AMERICAN MEDICAL ASSOCIATION: Dr. George F. Lull, 535 North Dearborn St., Chicago 10, Secretary.

1953 Clinical Session, St. Louis, Dec. 1-4.
1954 Annual Session, San Francisco, June 21-25.
1954 Clinical Session, Miami, Florida, Nov. 30-Dec. 3.
1955 Annual Session, Atlantic City, N. J., June 6-10.
1955 Clinical Session, Boston, Nov. 29-Dec. 2.

American Association of Obstetricians, Gynecologists and Abdominal Surgeons, The Homestead, Hot Springs, Va., Sept. 10-12. Dr. William F. Mengert, 2211 Oak Lawn Ave., Dallas, Texas, Secretary.

American Congress of Physical Medicine, Palmer House, Chicago, Aug. 31-Sept. 4. Dr. Walter J. Zeiter, 30 North Michigan Ave., Chicago 2, Executive Director.

American Dietetic Association, Los Angeles, Aug. 24-28. Miss Ruth M. Yakel, 620 N. Michigan Ave., Chicago 11, Executive Secretary.

American Electroencephalographic Society, Commander and Continental Hotels, Cambridge, Mass., Aug. 17-22. Dr. John A. Abbott, Massachusetts General Hospital, Boston 14, Secretary.

American Hospital Association, San Francisco, Aug. 31-Sept. 3. Mr. George Bugbee, 18 East Division St., Chicago 11, Executive Director.

American Society for Pharmacology and Experimental Therapeutics. Fall Meeting, Yale University, New Haven, Conn., Sept. 7-9. Dr. Carl C. Pfeiffer, 1853 West Polk St., Chicago 12, Secretary.

Biological Photographic Association, Hotel Statler, Los Angeles, Aug. 31-Sept. 3. Miss Jane H. Waters, 533 West 57th St., New York 19, Secretary.

Gerontological Society, Mark Hopkins Hotel, San Francisco, Aug. 25-27. Dr. Nathan W. Shock, Baltimore City Hospitals, Baltimore 24, Secretary.

Montana Medical Association, Northern Hotel, Billings, Sept. 17-20. Mr. L. R. Hegland, 104 North Broadway, Billings, Executive Secretary.

National Medical Association, Nashville, Tenn., Aug. 10-14. Dr. John T. Givens, 1108 Church St., Norfolk 10, Va., Executive Secretary.

North Pacific Society of Internal Medicine, Harrison, B. C., Sept. 18-19. Dr. Clarence C. Pearson, 1115 Terry Ave., Seattle 1, Wash., Secretary.

Regional Meetings, American College of Physicians:
North Dakota, Fargo, Sept. 12. Dr. Robert B. Radl, 221 Fifth St., Bismarck, Governor.
Arkansas-Oklahoma, Oklahoma City, Sept. 19. Dr. Wann Langston, 117 North Broadway, Oklahoma City 2, Governor.

Society of American Bacteriologists, Palace Hotel, San Francisco, Aug. 10-14. Dr. John H. Bailey, Sterling-Winthrop Research Institute, Rensselaer, N. Y., Secretary.

U. S. Chapter, International College of Surgeons, Waldorf-Astoria, New York, Sept. 13-17. Dr. Karl Meyer, 1516 Lake Shore Drive, Chicago 10, Secretary.

Utah State Medical Association, Salt Lake City, Sept. 10-12. Dr. Homer E. Smith, 42 South Fifth East St., Salt Lake City 2, Secretary.

Washington State Medical Association, Olympic Hotel, Seattle, Sept. 13-16. Dr. Bruce Zimmerman, 338 White-Henry-Stuart Bldg., Seattle 1, Secretary.

FOREIGN

Association of Surgeons of Great Britain and Ireland, Leeds, England, May 13-15, 1954. Dr. Henry W. S. Wright, 45 Lincoln's Inn Fields, London W.C.2, England, Honorary Secretary.

Canadian Medical Association, Vancouver, B. C., Canada, June 18-22, 1954. Dr. T. C. Routley, 135 St. Clair Ave. W., Toronto 5, Ont., Canada, General Secretary.

Congress of International Anesthesia Research Society, Chateau Frontenac, Quebec, Canada, October 26-29. Dr. A. William Friend, 515 Nome Ave., Akron 20, Ohio, Chairman, Program Committee.

Congress of the International Association of Limnology, Cambridge and Windermere, England, Aug. 20-30. For information write: Professor G. C. Hutchinson, Osborn Zoological Laboratory, Yale University, New Haven, Conn., U. S. A.

Congress of the International League Against Rheumatism, Geneva, Switzerland and Aix-les-Bains, France, Aug. 23-29. For information write: Dr. W. Tegner, The London Hospital, London E.1, England.

Congress of the International Society of Angiology, Lisbon, Portugal, Sept. 18-20. Dr. Henry Haimovici, 105 East 90th St., New York 28, N. Y., U. S. A., Secretary.

Congress of the International Society of Surgery, Lisbon, Portugal, Sept. 14-20. Dr. L. Dejardin, 141, rue Belliard, Brussels, Belgium, General Secretary.

Interim Meeting, Aero Medical Association, University of Brussels Medical School, Brussels, Belgium, Sept. 24-27. Dr. Andre Allard, Medical Director of SABENA, 145 Rue Royale, Brussels, Belgium, Secretary.

International Cancer Congress, Sao Paulo, Brazil, July 23-29, 1954. Prof. A. Prudente, 171 rua Benjamin Constante, Sao Paulo, Brazil, President.

International Conference on Thrombosis and Embolism, Basle, Switzerland, July 15-19, 1954. Dr. W. Merz, Chief Medical Officer, Gynecological Clinic, University of Basle, Basle, Switzerland, Hon. Secretary.

International Congress of Acupuncture, Kolpinghaus, Adolf-Kolping-Strasse 1, Munich, Germany, August 22-25. Dr. G. Bachmann, 29 Lilienstrasse, München 9, Germany, Organizer and Secretary.

International Congress of Electroencephalography and Clinical Neurophysiology, Boston, Mass., U. S. A., Aug. 18-21. Dr. Robert S. Schwab, Massachusetts General Hospital, Boston 14, Mass., U. S. A., Secretary-General.

International Congress of the European Society of Haematology, Amsterdam, Holland, Sept. 8-12. Dr. M. C. Verloop, Maliesingle 15, Utrecht, Holland, Secretary.

International Congress on Genetics, Bellagio, Italy, August 24-31. Prof. C. Barigozzi, Instituto de Genetica, Universita de Milano, 10 via Celoria, Milan, Italy, Secretary.

International Congress of Hippocratic Medicine, Evian, France, Sept. 3-6. Prof. P. Delore, 13, rue Jarente, Lyon, France, Secretary-General.

International Congress for History of Science, Jerusalem, Israel, August 3-7. Prof. F. S. Bodenheimer, Hebrew University, Jerusalem, Israel, President.

International Congress of Hydroclimatism and Thalassotherapy, Dubrovnik, Yugoslavia, May 8-16, 1954. Prof. C. Plavsic, Zeleni Venac 1, Belgrade, Yugoslavia, Secretary General.

International Congress of International College of Surgeons, Sao Paulo, Brazil, April 26-May 2, 1954. Dr. Max Thorek, 1516 Lake Shore Drive, Chicago, Illinois, U.S.A., Secretary-General.

International Congress of Logopedics and Phoniatrics, Zurich, Switzerland, Sept. 1-5. Dr. Deso A. Weiss, 115 East 86th St., New York 28, N. Y., U. S. A., General Secretary.

International Congress on Mental Health, University of Toronto, Toronto, Ontario, Canada, Aug. 14-21, 1954. For information write: Executive Officer, International Congress on Mental Health, 111 St. George St., Toronto, Ontario, Canada.

International Congress of Microbiology, Rome, Italy, Sept 6-12. For information write: Dr. V. Puntoni, Citta Universitaria, Rome, Italy.

International Congress on Obstetrics and Gynecology, Geneva, Switzerland, July 26-31, 1954. Dr. H. de Watteville, Maternité Hôpital Cantonal, Geneva, Switzerland, President.

International Congress of Paediatrics, Havana, Cuba, Oct. 12-17. Prof. Felix Hurtado, 5a Avenue 124, Miramar, Havana, Cuba, President.

International Congress of Psychology, Montreal, Canada, June 7-12, 1954. For information write: Prof. H. S. Langfeld, International Union of Scientific Psychology, Eno Hall, Princeton University, Princeton, N. J., U. S. A.

International Congress for Psychotherapy, Zurich, Switzerland, July 21-24, 1954. Dr. H. K. Fierz, Theaterstrasse 12, Zurich 1, Switzerland, Secretary General.

International Congresses of Tropical Medicine and Malaria, Istanbul, Turkey, Aug. 28-Sept. 4. Professor Dr. Ihsan Sükrü Aksel, Tunel Meydam, Beyoglu, Istanbul, Turkey, General Secretary.

International Congress of Zoology, Copenhagen, Denmark, Aug. 5-12. Dr. Anton F. Bruun, The University, Copenhagen, Denmark, Secretary General.

International Gerontological Congress, London and Oxford, England, July 12-22, 1954. Prof. R. E. Tunbridge, General Infirmary, Department of Medicine, The University, Leeds, England, President.

International Leprosy Congress, Madrid, Spain, Oct. 3-10. Dr. Felix Contreras, Moreto 15, Madrid, Spain, Secretary.

International Neurological Congress, Lisbon, Portugal, Sept. 7-12. Prof. Almeida Lima, Avenida do Brazil 53, Lisbon, Portugal, Secretary-General.

International Office of Documentation of Military Medicine, Rome, Italy, Oct. 14-18. Colonel Medecin Prof. A. Campana, Office of the Ministero della Difesa-Esercito, Rome, Italy, Secretary.

International Physiological Congress, Montreal, Canada, Aug. 31-Sept. 4. Dr. A. S. V. Burgen, Dept. of Physiology, McGill University, Montreal, Canada, Secretary.

International Psycho-Analytical Congress, Bedford College, Regent's Park, London N.W.1, England, July 26-30. Dr. Ruth S. Eissler, 285 Central Park West, New York 24, N. Y., Hon. Secretary.

International Society for the Study of Biological Rhythms, Basle, Switzerland, Sept. 18-19. For information write: Prof. Dr. F. Georgi, Neurologische Universitats-Poliklinik, Socinstrasse 55, Basle, Switzerland.

International Veterinary Congress, Stockholm, Sweden, Aug. 9-15. Prof. Axel Isaksson, Institute of Veterinary Medicine, Stockholm 50, Sweden, Secretary.

Journees Medicales, Paris, France, April 21-25, 1954. For information write: Secretariat of the Journees, 12, rue Pierre-Geofroix, Colombes (Seine) France.

Latin American Congress of Obstetrics and Gynecology, Buenos Aires, Argentina, Oct. 26-31.

Latin American Congress of Otorhinolaryngology, Caracas, Venezuela, Feb. 21-25, 1954. Dr. Victorino Marquez Reveron, Centro Medico, Caracas, Venezuela, Secretary-General.

Pacific Science Congress, Quezon City and Manila, Philippines, Nov. 16-28. Dr. Patrocinio Valenzuela, College of Pharmacy, University of the Philippines, Quezon City, Philippines, Secretary-General.

Pan American Congress of Otorhinolaryngology and Bronchoesophagology, Mexico, D.F., Mexico, Feb. 28-March 4, 1954.

Pan American Medical Women's Alliance, Beekman Towers Hotel, New York, N. Y., Sept. 24-Oct. 1. Dr. Ina Marsh, 140 Linwood Ave., Buffalo, N. Y., U. S. A., Registration Chairman.

Persian Gulf Medical Society, Dhahran, Saudi Arabia, Dec. 7-8. Dr. N. J. Conan Jr., Department of Internal Medicine, Arabian American Oil Company, Dhahran, Saudi Arabia, Secretary.

Sectional Meeting, American College of Surgeons, London, England, May 17-19, 1954. Dr. Michael L. Mason, 40 East Erie St., Chicago 11, Ill., U. S. A., Secretary.

World Conference on Medical Education, British Medical Association House, Tavistock Square, W.C.1, London, England, Aug. 22-29. Secretariat: World Medical Association, 2 East 103d St., New York 29, N. Y., U. S. A.

World Congress of the World Confederation for Physical Therapy, London, England, Sept. 7-12. Miss M. J. Neilson, Chartered Society of Physiotherapy, Tavistock House, South, Tavistock Square, London, W.C.1, England, Secretary.

World Federation for Mental Health, Vienna, Austria, Aug. 17-23. For information write: Miss E. M. Thornton, 19 Manchester St., London, W.1, England.

World Medical Association, The Hague, Netherlands, Aug. 31-Sept. 7. Dr. Louis H. Bauer, 345 East 46th St., New York 17, N. Y., Secretary-General.

EXAMINATIONS AND LICENSURE

BOARDS OF MEDICAL EXAMINERS

Alaska:* Anchorage and Juneau, Sept. 7. Sec., Dr. W. M. Whitehead, 172 South Franklin St., Juneau.

Guam: The Commission on Licensure will meet whenever a candidate appears or submits his credentials. Ex. Sec., Dr. Austin W. Matthis, Agana.

Montana: Helena, Oct. 5. Sec., Dr. S. A. Cooney, 214 Power Block, Helena.

New Hampshire: Concord, Sept. 9. Sec., Dr. John S. Wheeler, 107 State House, Concord.

New Mexico:* Oct. 12-13, Santa Fe. Sec., R. C. Derbyshire, 227 E. Palace Ave., Santa Fe.

North Carolina: *Reciprocity*. Blowing Rock, Aug. 1. Sec., Dr. Joseph J. Combs, 716 Professional Bldg., Raleigh.

Pennsylvania: *Examination*. Philadelphia and Pittsburgh, July. Act. Sec., Mrs. Margaret G. Steiner, Box 911, Harrisburg.

Texas: Fort Worth, Nov. 12-14. Reciprocity applicants must be completed 30 days prior to the meeting date. Sec., Dr. M. H. Crabb, 1714 Medical Arts Bldg., Fort Worth 2.

Utah: *Examination*. Salt Lake City, July. Asst. Dir., Mr. Frank E. Lees, 324 State Capitol Bldg., Salt Lake City.

Puerto Rico: *Reciprocity*. Santurce, Aug. 4. Sec., Mr. Luis Cueto Coll, Box 9156, Santurce.

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Alaska: On application. Juneau or other towns in Territory as decided by Board. *Reciprocity*. On application. Sec., Dr. C. Earl Albrecht, Box 1931, Juneau.

Colorado: *Examination*. Denver, Sept. 9-10. Sec., Dr. Esther B. Starks, 1459 Ogden St., Denver 18.

District of Columbia: *Examination*. Washington, Oct. 19-20. Sec., Dr. Daniel L. Seckinger, 4130 E. Municipal Bldg., Washington.

Oklahoma: *Examination*. Oklahoma City, August 28-29. Sec., Dr Clinton Gallaher, 813 Braniff Bldg., Oklahoma City.

Oregon: Portland, Aug. 29. Final date for filing application is Aug. 12. Portland, Dec. 5. Sec., Dr. Charles D. Byrne, University of Oregon, Eugene.

Texas: *Examination*. Austin, October. Chief Clerk, Mrs. Sandra Allen, 407 Perry-Brooks Bldg., Austin.

Wisconsin: *Examination*. Madison, Sept. 19. Final date for filing application is Sept. 11. Milwaukee, Dec. 5. Final date for filing application is Nov. 27. Sec., Dr. W. H. Barber, 621 Ransom St., Ripon.

---

* Basic Science Certificate required.

DEATHS

Smith-Petersen, Marius Nygaard ⊕ Boston; born in Grimstad, Norway, Nov. 14, 1886; Harvard Medical School, Boston, 1914; from 1920 to 1930 assistant instructor of orthopedic surgery at his alma mater, where he was instructor from 1930 to 1935 and from 1935 to 1946 clinical professor of orthopedic surgery; specialist certified by the American Board of Orthopaedic Surgery; member and past president of the American Academy of Orthopaedic Surgeons; member of the American Orthopaedic Association, International Society of Surgery, International Society of Orthopedic Surgery, Boston Surgical Society, New England Surgical Society, and Phi Beta Kappa; honorary member of the British and Canadian orthopedic associations, Italian Society of Orthopaedics and Traumatology, and the Royal Medical Society of Edinburgh; fellow of the American College of Surgeons; decorated with the Grand Cross of the Royal Norwegian Order of St. Olav; Commander of the Royal Order of St. Olav (Norway); chief of the orthopedic service of the Massachusetts General Hospital from 1929 to 1946; received an honorary M.D. degree from the University of Oslo, Norway; developed the Smith-Petersen nail, a flanged nail for fixing the head of the femur in fracture of the femoral neck; died in Phillips House of the Massachusetts General Hospital June 16, aged 66, of coronary occlusion.

Barney, Louie Frank ⊕ Kansas City, Kan.; born in Cherokee, Kan., Nov. 19, 1876; Kansas City (Mo.) Medical College, 1903; emeritus associate professor of clinical surgery at the University of Kansas School of Medicine, Kansas City, Kan.; member of the House of Delegates of the American Medical Association in 1928, 1930, and 1932; past president of the Kansas Medical Society, Wyandotte County Medical Society, Kansas City Surgical Society, and the Kansas City Academy of Medicine; served as first and second vice-president of the Kansas City Southwest Clinical Society, of which he was one of the organizers; member of the Western Surgical Association and the Industrial Medical Association; fellow of the American College of Surgeons; member of the founders' group of the American Board of Surgery; a captain in the medical corps of the U. S. Army during World War I; affiliated with St. Margaret's Hospital, where he was past president of the hospital staff; member of the staffs of Bethany and Providence hospitals; died June 1, aged 76, of cerebral hemorrhage.

Charlton, H. Richard ⊕ Bronxville, N. Y.; born in New York City Nov. 8, 1877; Columbia University College of Physicians and Surgeons, New York, 1901; an Associate Fellow of the American Medical Association; veteran of the Spanish-American War and World War I; on May 16, 1944, received the second James Ewing award from the Westchester County Medical Society "as a token of recognition and commendation for distinguished service to the people and to the medical profession of Westchester County contributing to the understanding and control of malignant disease"; for many years affiliated with Lawrence Hospital; died May 14, aged 75, of asthma and chronic myocarditis.

S. Army, from 1917 to 1922; served on the staffs of the Mount Sinai Hospital and Clinic, Los Angeles County General Hospital, and Cedars of Lebanon Hospital; author of "Fungous Diseases," 1932; died March 21, aged 64, of hypertension and cerebral hemorrhage.

Perry, Middleton Lee ⊕ Topeka, Kan.; born in Lancaster, Texas, Aug. 15, 1868; University of Tennessee Medical Department, Nashville, 1892; member of the American Psychiatric Association and the Central Neuropsychiatric Association; in 1924 member of the House of Delegates of the American Medical Association; in 1922 president of the Kansas Medical Society; at one time superintendent of the State Hospital for Epileptics in Parsons; for 30 years superintendent of the Topeka State Hospital, retiring from that post in 1948; affiliated with Stormont-Vail Hospital and St. Francis Hospital; died April 11, aged 84, of heart disease.

Abrons, Harry ⊕ Berkeley, Calif.; Columbia University College of Physicians and Surgeons, New York, 1909; member of the American Academy of General Practice; served on the staff of Herrick Memorial Hospital; died in New York June 4, aged 70, of angina pectoris.

Bartlett, Alexander George ⊕ San Francisco; University of California Medical School, San Francisco, 1926; assistant clinical professor of medicine at his alma mater; specialist certified by the American Board of Internal Medicine; served during World Wars I and II; affiliated with Franklin Hospital, where he died May 28, aged 58.

Baumgartner, Albert J., Elkhart, Ind.; Cincinnati College of Medicine and Surgery, 1894; died March 25, aged 85, of coronary vascular disease and arteriosclerosis.

Bayles, Lewis Eugene ⊕ Anderson, Ala.; University of Alabama School of Medicine, 1911; vice-president of the Farmers Bank; died in Florence May 23, aged 69, of coronary thrombosis.

Berresheim, Frieda K. Manfred ⊕ Louisville, Ky.; Medizinische Fakultät der Universität, Vienna, Austria, 1919; specialist certified by the American Board of Obstetrics and Gynecology; on the staffs of St. Joseph's Infirmary, Kentucky Baptist Hospital, and St. Anthony's Hospital, where she died March 22, aged 57, of hypertensive cardiorenal disease and coronary insufficiency.

Bowen, Berry, Seattle; University of Louisville (Ky.) Medical Department, 1890; died May 26, aged 85.

Bowman, J. Craig ⊕ Upper Sandusky, Ohio; Rush Medical College, Chicago, 1912; member of the American Academy of General Practice; past president and secretary of the Wyandot County Medical Society; served during World War I; major, medical reserve corps of the U. S. Army; affiliated with Wyandot Memorial Hospital, where he died May 6, aged 65, of coronary occlusion and mesenteric embolism.

Bryant, Frank Adolph ⊕ Colfax, Wash.; University of Louisville (Ky.) School of Medicine, 1911; past president of the Whitman County Medical Society; served during World War I; for many years county health officer; died April 15, aged 69, of heart disease.

Caskey, Walter Harold ⊕ Pittsburgh; University of Pittsburgh School of Medicine, 1909; for many years chief medical inspector for the city bureau of infectious diseases; died in Pittsburgh Hospital May 24, aged 67, of cerebral thrombosis.

Chace, Fenner Albert ⊕ Chevy Chase, Md.; Harvard Medical School, Boston, 1905; member of the Massachusetts Medical Society, American Academy of Dermatology and Syphilology and the New England Dermatological Society; formerly practiced in Fall River, Mass.; died June 4, aged 78, of chronic suppurative cholangitis, hypoplastic anemia, and carcinoma.

Chandeysson, Pierre Ismail, St. Louis; Washington University School of Medicine, St. Louis, 1901; physician and president of Chandeysson Electric Company; served in the French, British, and U. S. armies during World War I; died in the Alexian Brothers Hospital June 5, aged 77.

Clowes, Leo Clifford ⊕ Hinsdale, Ill.; Rush Medical College, Chicago, 1923; served as instructor in surgery at the University of Illinois College of Medicine in Chicago, where he was on the staff of the Cook County Hospital; on the staff of the

---

⊕ Indicates Member of the American Medical Association.

Hinsdale Sanitarium; drowned June 10, aged 62, when he was swept into deep water by swollen currents in the Fox River near Millbrook, while fishing.

Collins, Loren Leslie ⊕ Edwardsville, Ill.; born in Wilkes-Barre, Pa., Oct. 24, 1890; University of Illinois College of Medicine, Chicago, 1925; member of the American Trudeau Society; past president of the Mississippi Valley Trudeau Society; superintendent and medical director of the Madison County Tuberculosis Sanatorium; formerly medical director and executive of the La Salle County Tuberculosis Sanatorium in Ottawa; died in the Passavant Memorial Hospital, Chicago, May 1, aged 52, of heart disease.

Cox, Frank Edwin, Milwaukee; Milwaukee Medical College, 1910; died recently, aged 70, of cerebral hemorrhage.

Craft, Harry Leolyn ⊕ Ashfield, Mass.; University of Vermont College of Medicine, Burlington, 1906; an Associate Fellow of the American Medical Association; medical examiner for Franklin County; on the courtesy staffs of the Franklin County Hospital in Greenfield and the Cooley Dickinson Hospital in Northampton, where he died May 19, aged 74, of injuries received in an automobile accident.

Curtin, Thomas Hayes ⊕ New York City; Bellevue Hospital Medical College, New York, 1897; at one time on the faculty of the Fordham University School of Medicine and the New York Polyclinic Medical School and Hospital; an officer in France during World War I; affiliated with the Bronx Eye and Ear Infirmary and formerly with Manhattan Eye, Ear and Throat Hospital; died in New York Hospital June 3, aged 78, of injuries received in a taxicab accident.

Davis, William ⊕ Akron, Ohio; Ohio State University College of Medicine, Columbus, 1934; member of the American Academy of General Practice; served during World War II; died May 8, aged 46, of heart disease.

Dowling, Thomas J. Detroit; Detroit College of Medicine, 1904; died in the Grace Hospital April 24, aged 73, of cerebral hemorrhage.

Durant, Oswald Davidson, Alexandria, Va.; Meharry Medical College, Nashville, Tenn., 1926; died April 10, aged 57, of coronary occlusion and hypertension.

Evans, Alfred Harris ⊕ Chattanooga, Tenn.; University of Tennessee College of Medicine, Memphis, 1948; affiliated with Currey Clinic; died May 27, aged 31, of reticulum cell sarcoma.

Gehris, Oscar Thompson ⊕ Fleetwood, Pa.; Tufts College Medical School, Boston, 1898; died in St. Joseph's Hospital, Reading, May 28, aged 82, of postoperative shock.

Goldfarb, Walter ⊕ New York City; Yale University School of Medicine, New Haven, Conn., 1935; certified by the National Board of Medical Examiners; specialist certified by the American Board of Psychiatry and Neurology; fellow of the American College of Physicians; member of the American Psychiatric Association; served during World War II; died June 5, aged 43.

Gruhler, Jean Albert ⊕ Atlantic City, N. J.; University of Pennsylvania School of Medicine, Philadelphia, 1933; served during World War II; died in Ventnor, May 29, aged 45.

Haberer, Herman Joseph ⊕ Utica, N. Y.; College of Physicians and Surgeons, Baltimore, 1906; for many years county coroner; on the staff of St. Luke's Hospital; died May 30, aged 72, of congestive heart failure.

Haley, Michael Robert ⊕ Dayton, Ohio; St. Louis University School of Medicine, 1913; specialist certified by the American Board of Internal Medicine; fellow of the American College of Physicians; served in France during World War I; affiliated with St. Elizabeth Hospital and the Good Samaritan Hospital, where he died May 28, aged 68, of cerebral hemorrhage.

Hansen, Otto Anthon, Forest City, Iowa; State University of Iowa College of Homeopathic Medicine, Iowa City, 1896; for many years member of the library board; served on the school board; died April 5, aged 88, of cerebral accident.

Hastings, John Charles, Orlando, Fla.; Rush Medical College, Chicago, 1902; died April 2, aged 78.

Hawkins, George Giles ⊕ Madera, Calif.; Washington University School of Medicine, St. Louis, 1905; served during World War I; died in the VA Hospital, Fresno, April 16, aged 72, of carcinoma of the lung.

Heard, Mary Kathrina, St. Petersburg, Fla.; State University of Iowa College of Medicine, Iowa City, 1905; member of the American Academy of Ophthalmology and Otolaryngology; died April 20, aged 83, of cerebral thrombosis.

Hearn, Arthur C., Baltimore; University of Maryland School of Medicine, Baltimore, 1897; died April 19, aged 79, of occlusion of the coronary artery and arteriosclerosis.

Hilt, John Leonard ⊕ Lineville, Ala.; Southern Medical College, Atlanta, 1889; died in Clay County Hospital, Ashland, May 24, aged 90, of bronchopneumonia.

Hoffman, Curtis Raymond ⊕ Richmond, Ind.; Indiana University School of Medicine, Indianapolis, 1925; served during World War I; affiliated with Reid Memorial Hospital; died April 22, aged 57, of heart disease.

Hughes, Herbert Andrew ⊕ La Mesa, Calif.; University of Oregon Medical School, Portland, 1939; specialist certified by the American Board of Radiology; member of the Radiological Society of North America and the American College of Radiology; died in San Diego March 20, aged 47, of rheumatic heart disease.

Hughes, Lawrence Jesse ⊕ Elgin, Ill.; Rush Medical College, Chicago, 1902; past president of the Kane County Medical Society; on the staffs of the St. Joseph Hospital and the Sherman Hospital, where he died May 20, aged 73, of coronary thrombosis.

Ison, Gideon Douglas, Bonita Springs, Fla.; University of Louisville (Ky.) Medical Department, 1908; died in Atlanta, Ga., April 5, aged 72.

Ives, Augustus W., Alexandria, Va.; Detroit College of Medicine, 1891; emeritus professor of neurology at Wayne University College of Medicine in Detroit; formerly practiced in Detroit, where he was affiliated with St. Mary's, William Booth Memorial, and Providence hospitals; died April 4, aged 92, of cerebral hemorrhage.

Jennings, John Buford ⊕ Peoria, Ill.; Chicago College of Medicine and Surgery, 1916; on the staff of the Proctor Hospital, where he died May 22, aged 62, of uremia and gastric hemorrhage.

Jordan, John Franklin ⊕ Peabody, Mass.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1900; an Associate Fellow of the American Medical Association; died in Josiah B. Thomas Hospital May 21, aged 85.

Kermek, Ace, Brooklyn; Université de Paris Faculté de Médecine, France, 1899; at one time U. S. consular representative in Bulgaria; served in the Bulgarian Army during World War I; formerly on the staffs of the Lutheran, Unity, and Adelphi hospitals; died April 29, aged 82, of carcinoma of the descending colon.

Kistler, Milton S., St. Louis; Hahnemann Medical College and Hospital of Philadelphia, 1892; died April 1, aged 83.

Love, George Melvin ⊕ Rogers, Ark.; born in 1873; Kansas City (Mo.) Hahnemann Medical College, 1909; past president of the Benton County Medical Society; honorary life president of the Benton County Tuberculosis Association, of which he was president for many years; formerly secretary of the Homeopathic State Medical Board; served as president of the board of education and as a member of the city council; elected chief of the fire department on its reorganization, holding that position until his retirement; died May 30, aged 79.

Lukens, Philip Jefferson ⊕ Ambler, Pa.; Medico-Chirurgical College of Philadelphia, 1913; past president of the Montgomery County Medical Society and the Philadelphia Medical Club; died in the Abington (Pa.) Memorial Hospital June 6, aged 62, of coronary infarction.

McCormack, James L. ⊕ Newton, Ill.; St. Louis College of Physicians and Surgeons, 1892; served as county coroner; died May 30, aged 88, of pulmonary edema.

McCoy, Clem Dennin, Kenton, Ohio; Rush Medical College, Chicago, 1890; died in Hardin Memorial Hospital May 19, aged 88, of arteriosclerotic heart disease.

Martin, Frank DeWees ⊕ Bedford, Ind.; Indiana University School of Medicine, Indianapolis, 1914; past president of the Lawrence County Medical Society; served during World War I; died May 18, aged 62, of chronic myocarditis and myocardial degeneration.

Miller, Bodo Emanuel ⊕ Akron, Ohio; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1911; served during World War I; died in the City Hospital June 3, aged 67, of carcinoma of the prostate.

Mitchener, James Samuel Sr. ⊕ Raleigh, N. C.; Johns Hopkins University School of Medicine, Baltimore, 1915; died March 18, aged 64, of cerebral hemorrhage.

Moore, Phoebia Gean ⊕ Mannington, W. Va.; Illinois Medical College, Chicago, 1903; died in Fairmont June 3, aged 81.

Morison, Oscar Noel ⊕ Charleston, W. Va.; University of Virginia Department of Medicine, Charlottesville, 1928; served as senior psychiatrist at the Essex County Overbrook Hospital in Cedar Grove, N. J., and the Hartford (Conn.) Retreat; died June 6, aged 51, of the effects of burns sustained two days previously in a fire at his home.

Nelson, Harry Emanuel ⊕ Dayton, Iowa; Rush Medical College, Chicago, 1893; past president of the Webster County Medical Society; served on the school board, as mayor, and as member of the library board; died in the Mercy Hospital in Fort Dodge May 16, aged 83.

Nuzum, John Weston ⊕ Chicago; Rush Medical College, Chicago, 1914; fellow of the American College of Surgeons; on the staff of the Augustana Hospital, where he died June 14, aged 62, of bronchopneumonia.

Ogden, Lee ⊕ New York City; Ludwig-Maximilians-Universität Medizinische Fakultät, München, Bavaria, Germany, 1913; affiliated with Gouverneur Hospital; died in Greenwich, Conn., May 12, aged 65, of coronary thrombosis with myocardial infarction.

O'Neil, Alfred Eugene ⊕ Miami, Fla.; University of Cincinnati College of Medicine, Cincinnati, 1938; member of the American Academy of General Practice; died April 15, aged 55, of coronary thrombosis.

Peacock, Lee Wallace ⊕ Highland Park, Mich.; St. Louis University School of Medicine, 1923; died in Highland Park General Hospital May 20, aged 57, of cerebral hemorrhage.

Post, Cecil Omar ⊕ Clarksburg, W. Va.; born in Clarksburg in 1888; College of Physicians and Surgeons, Baltimore, 1912; member of the American Academy of General Practice; past president, secretary, and treasurer of the Harrison County Medical Society; councilor of the Southern Medical Association; served two terms as a member of the council of the West Virginia State Medical Association; on the staffs of St. Mary's and Union Protestant hospitals; died suddenly, June 11, aged 64, of coronary thrombosis.

Quinland, William Samuel ⊕ Tuskegee, Ala.; Meharry Medical College, Nashville, Tenn., 1919; specialist certified by the American Board of Pathology; member of the National Medical Association, American Association of Pathologists and Bacteriologists, and the College of American Pathologists; formerly on the faculty of his alma mater; affiliated with VA Hospital, where he died April 6, aged 67, of myocardial infarction and arteriosclerosis.

Reneke, Edward Joseph ⊕ Skygusty, W. Va.; University of Tennessee College of Medicine, Memphis, 1929; mine physician for the U. S. Steel Company; died May 7, aged 48, of coronary occlusion.

Robinson, Finley A. ⊕ Blytheville, Ark.; Memphis (Tenn.) Hospital Medical College, 1904; died March 26, aged 72, of coronary thrombosis.

Romano, Joseph James ⊕ Coral Gables, Fla.; Tufts College Medical School, Boston, 1929; served during World War II; on the staff of the VA Hospital; died March 26, aged 50.

Rosensohn, Meyer ⊕ New York City; Columbia University College of Physicians and Surgeons, New York, 1909; assistant professor of clinical obstetrics and gynecology at Cornell University Medical College; specialist certified by the American Board of Obstetrics and Gynecology; fellow of the American College of Surgeons; on the staff of the Bronx Hospital; died April 15, aged 71.

Sanders, John Gillis ⊕ Gulf Shores, Ala.; Tulane University of Louisiana School of Medicine, New Orleans, 1913; specialist certified by the American Board of Otolaryngology; member of the American Academy of Ophthalmology and Otolaryngology; served overseas during World War I; practiced in Foley and Mobile; served on the staffs of the Mobile Infirmary, City Hospital, and Providence Hospital in Mobile, where he died June 1, aged 61, of acute coronary occlusion.

Schroer, Harry T., Cincinnati; Miami Medical College, Cincinnati, 1902; died April 10, aged 72, of heart disease.

Schureman, Oliver Perry, Alhambra, Calif.; Washington University School of Medicine, St. Louis, 1934; served during World War II; died in Winston-Salem, N. C., April 28, aged 44.

Shagrin, Arthur W. ⊕ Cleveland; Western Reserve University School of Medicine, Cleveland, 1929; served during World War II; on the staff of the Mount Sinai Hospital, where he died May 23, aged 47, of myasthenia gravis.

Sheehan, George Augustine ⊕ Brooklyn; born in Lafayetteville, N. Y., in 1889; Fordham University School of Medicine, New York, 1913; specialist certified by the American Board of Internal Medicine; fellow of the American College of Physicians; clinical professor of medicine, State University of New York College of Medicine at New York City; affiliated with Norwalk (Conn.), St. Peter's, St. Mary's, Long Island College, and Kings County hospitals, and the Hospital of the Holy Family, where he died June 5, aged 63, of carcinoma of the pancreas.

Smith, Mary Hopkins, West Chester, Pa.; Woman's Medical College of Pennsylvania, Philadelphia, 1896; served as treasurer of the Chester County Medical Association; died May 17, aged 88, of bronchopneumonia.

Smith, Waldo Emerson ⊕ Decatur, Ind.; Ohio Medical University, Columbus, 1906; died in the Adams County Memorial Hospital April 9, aged 81, of cerebral hemorrhage.

Stafford, Harry Howard, Dayton, Ohio; Ohio Medical University, Columbus, 1907; died May 30, aged 77.

Strain, Earle ⊕ Great Falls, Mont.; University of Pennsylvania Department of Medicine, Philadelphia, 1890; fellow of the American College of Surgeons; honorary life member of the Montana Academy of Oto-Ophthalmology; affiliated with Deaconess and Columbus hospitals; died June 1, aged 84, of heart disease.

Sumner, Roy S., Owensboro, Ky.; Louisville and Hospital Medical College, 1908; served during World War I; affiliated with Owensboro-Daviess County and Our Lady of Mercy hospitals; died recently, aged 69, of coronary occlusion.

Sybert, George Bradley, Ellicott City, Md.; Johns Hopkins University School of Medicine, Baltimore, 1923; died in St. Joseph's Hospital, Baltimore, April 27, aged 54, of retroperitoneal reticulum cell sarcoma.

Talbott, Thomas John ⊕ Lima, Ohio; Ohio State University College of Medicine, Columbus, 1943; served during World War II; for many years county coroner; on the staff of Lima Memorial and St. Rita's hospitals; died April 17, aged 37, of injuries received in an automobile accident.

Utter, John William, Anaheim, Calif.; University of California Medical School, San Francisco, 1910; formerly on the staff of St. Joseph's Hospital in Orange; died May 12, aged 80, of arteriosclerosis.

FOREIGN LETTERS

BELGIUM

Congress of Surgery.—The Sixth Belgian Congress of Surgery was held in 1952 at Brussels under the presidency of Dr. Bonzon. Two questions received special study.

The Pathology of the Diaphragm.—Van der Stricht discussed the morphology of the normal and the abnormal diaphragm, including tumors, hernias, and eventrations. Deloyers devoted his paper to the clinical study of diaphragmatic conditions. Harrington proposed classifying hernias in two groups, traumatic and nontraumatic. The following order of frequency of hernias has been noted: (1) esophageal hiatus hernias (60 to 80%); (2) traumatic hernias, direct or indirect, and those caused by necrosis; (3) hernias resulting from the absence of a part of the diaphragm; (4) hernias from pleuroperitoneal hiatus; and (5) subcostosternal hernias (of the foramen of Morgagni).

Hiatus hernias can be demonstrated radiologically. Most radiologists are able to demonstrate the lesion with the patient in a ventral position, preferably in right lateral decubitus position. Esophagoscopic examination is an indispensable adjunct in the diagnosis of diaphragmatic hiatus hernias.

Antithyroid Drugs and Thyroid Pathology.—Synthetic antithyroid substances constitute a great advance in antithyroid therapy. In some cases a definitive cure can be achieved with these drugs. The operative indications detailed by Bastenie and Flamand must be considered with this in mind. They conclude that medical treatment should be reserved for juvenile hyperthyroid disease, mild hyperthyroid disease, elderly patients, patients with asystole, and patients who have relapsed following surgical treatment. When adequate technical facilities are available, radioactive iodine should be used in treating patients over 55 years old. Other patients should be given antithyroid substances in doses varying with the stage of the disease.

An acceptable, though not ideal, indication for treatment by antithyroid substances, provided adequate control can be established, is the refusal of the patient to submit to operation. Estrogens, *p*-hydroxypropriophenone, and cortisone are useful weapons in certain special cases, but scarcely ever constitute the sole basis of treatment. In most cases of hyperthyroidism, subtotal thyroidectomy after scrupulous preparation, sometimes continued for several months, remains the treatment of choice. Preparation with thyroid-inhibitors, especially propylthiouracil, has increased the safety of surgical treatment to an astonishing degree and has made operation possible for many patients who would formerly not have been considered eligible for surgery.

The Fight Against Cancer in Belgium.—At the last *Journées Médicales* of Brussels, Drapier discussed the activities of the Belgian National Society for the Fight Against Cancer. The need for systematic organization of the fight against cancer must be presented to the whole nation every day, particularly since the nature of cancer remains mysterious. The author showed that the Belgian National Society for the Fight Against Cancer has fulfilled the first requirement for success. He pointed out that in 1950 there were 12,624 deaths due to cancer, 2,943 to pulmonary tuberculosis, 794 to other forms of tuberculosis, 98 to syphilis, and 24 to poliomyelitis. The society is making an appeal for the facilities that are indispensable for correct care of cancer patients, so that the four university centers may be properly supplied. It has a library, which makes it possible for all physicians to inform themselves on any aspect of cancer. The speaker presented a budgetary estimate and urgently requested the support of the authorities.

Control of Pharmaceutical Products.—Before the Belgian Society of Legal Medicine (March, 1953, session), the pharmacist Laurent lectured on the highly controversial question of the control of pharmaceutical products and explained the initiative taken by the professional association of Belgian pharmacists.

This association has signed a contract (unique in the world) with the principal drug manufacturers, assuming responsibility and guaranteeing prompt action in cases in which a product ought to be withdrawn from the market. In fact, from the official and governmental point of view, the manufacture of drugs is absolutely uncontrolled in Belgium; no guarantee, no license, and no proof of competence are required of the producer. The pharmacist assumes responsibility for the medicament he delivers. He should therefore be able to guarantee the composition of the products sold in his pharmacy as well as that of the prescriptions he compounds. Although he has a civil, penal, and ethical responsibility, it is not possible for him to test all the drugs. It is to meet this problem that control has been organized by the professional association.

Control can be exercised in connection with production; this is done by large firms employing numerous university-trained men to test the constancy of the value of their products. Control by a neutral and independent organization is also possible, and, finally, the pharmacist can make the tests at the time of dispensing the product. These private undertakings have less value than a supervised organization, however. Thanks to funds raised in professional circles, the pharmacists now have at their disposal laboratories provided with the most advanced equipment for chemical, microchemical, and bacteriological analysis. In addition to older methods of analysis, the most modern techniques can be employed. In addition, the organization appeals in certain cases to the university laboratories for assistance.

For the year 1952, the organization refused to guarantee 869 of the 1,855 products offered. An approved medication may be packed in a container bearing a registration stamp. This is, for the pharmacist, the physician, and the public in particular, a guarantee against inaccuracy in the declaration of the composition of the product, against imperfect and impure products, and against the inclusion of unmentioned drugs.

The Reform of Sickness Insurance.—A conflict has been in progress between the authorities, mutual benefit societies for medical care, and the medical profession. After prolonged discussions, the parties have arrived at a provisional understanding by accepting a solution that repudiates the state-controlled public service and permits autonomous administration of the separate funds with variable premium quotas and benefits. The same conflict exists in many countries; numerous professional groups are interested in this question, which is really the center of the whole future of medicine. Since each experience in this field may have an instructive value and since these experiences are being multiplied in all countries, it may be useful to compare various points of view. The solution accepted at present in Belgium has, however, been received with little favor by physicians, who are, properly enough, jealous in defending their professional solidarity.

The following are the principal directives and the major characteristics of the sickness-insurance reform. The insurance organizations are obliged to furnish certain basic benefits for such diseases as cancer, tuberculosis, and poliomyelitis and for intervention or procedures requiring the services of specialists, but they can determine as they wish the provision of other medical services, especially in general medicine. Physicians may or may not agree to care for the insured at the official rates; if they do, they appear on public lists. If they take part in the program, they are relieved of responsibility for professional secrecy in relation to consultants and come under the technical control of the insurance organizations.

The solution arrived at may be considered quite liberal, inasmuch as the autonomy of the organizations is carried to its logical conclusion in the matter of financial responsibility. The first rule, as a matter of fact, is freedom of choice by the insured of the insuring organizations, which exist in numbers

---

The items in these letters are contributed by regular correspondents in the various foreign countries.

corresponding to the various political and religious tendencies of the population. A National Fund for Sickness-Disability Insurance is charged with collecting the premium quotas and dividing them among the insuring organizations according to the duration of their policies and taking into account the salary, age, and sex of the insured, his family responsibilities, his professional field, and his residence, with consideration of objective evidence of unhealthy conditions in the region. A technical commission established by the administration defines the criteria of distribution.

To the funds derived from the quotas of the insured there has just been added an annual subsidy from the government, amounting in the general program to 16% of the revenue from the premium quotas allotted to the sickness-disability insurance. Nevertheless, the insuring organizations are responsible for administration of the funds. Their resources are to be available for financing services considered to have the highest priority, including major surgical procedures, obstetric care, hospitalization for over eight days, treatment of mental illness, cancer, tuberculosis, and poliomyelitis, provision of certain orthopedic apparatus and prostheses, certain radiological examinations, certain x-ray or radium treatments given by specialists, certain laboratory analyses, and finally certain neuropsychiatric benefits.

The receipts are also used to cover the administrative expenses and to finance, under conditions and at rates determined by the organizations, care other than that already listed, especially routine medical care (consultations and home calls from general practitioners or specialists, pharmaceutical supplies, preventive examinations, special care, and dental service). If, after this, the organization has a deficit, it may demand a supplemental premium from the insured.

The operation of the program is placed under the general control of the National Fund for Sickness-Disability Insurance, which acts through committees and councils. The committees are composed of delegates from the mutual benefit societies and persons belonging to the insuring organizations and representatives from the professional organizations of physicians and from the Ministries of Labor, Health, and Finance. In addition there is a medical council of physicians chosen by the insuring organizations, the professional organizations of physicians, and two physicians designated by the ministries of Labor and Health.

From the point of view of the practical accomplishment and operation of these services, the law prescribes the principle of free choice by the insured of his physician or his health institution. In the matter of fees, the compulsory benefits must be in accordance with the scales of honorariums and reimbursement fixed by the Ministry of Labor, which can modify them only on recommendation of the permanent committee. As for other services, they may be provided according to honorariums freely fixed by the practitioner, the rate of reimbursement being established by the insuring organizations according to their ability. The national fund publishes each year the list of practitioners agreeing to render priority services at the insurance rates to insured persons whose incomes do not exceed an amount fixed by decree. Professional secrecy is to be completely respected in principle. This does not prevent it from being completely effaced in the relations between practitioners and consultants. These last act as consultants, without being able to take the place of the physician in charge or to apply or impose the treatment they prescribe. They proceed in a friendly way and try to reconcile any differences that may arise.

Control of the operation is entrusted, not to the organization of physicians, but to a commission of medical discipline, on which there are, of course, physicians, but only in a minority. Furthermore, this commission has only a consultative role, since only the insuring organizations can establish the honorariums.

This scheme has been the object of protests from the Belgian Medical Federation, which emphasizes the fact that it is a caricature of sickness insurance, designed to serve as a springboard and means of recruitment for various political parties. So, again, the federation appeals to the medical profession to maintain unbroken solidarity.

ISRAEL

Convention on History of Medicine.—The third country-wide convention of the Society for the History of Medicine and the Natural Sciences was held recently in Tel Aviv. Twelve lectures were given on various topics relating to the history of medicine, chemistry, pharmacology, and theoretical physics. Three events formed the main background to the discussions. The first of these related to the false charges made against the Russian physicians, historicoscientific expression being given to this subject in lectures by Dr. S. Muntner in his review "Blood Libels Against Jewish Doctors in the History of Medicine" and by Dr. Dvorjetzky in his lecture "Scientific Papers by Jewish Doctors During the Period of the Holocaust." The second event was the seventh International Congress for the History of Science, due to meet in Jerusalem in August. Professor Bodenheimer gave some details on the progress of preparations for this congress, the first to be held in Israel. About 100 historicoscientific lectures are to be delivered at the congress. The third event was the organized registration of pharmacists in the society, in connection with which Dr. Yakar gave a lecture on "Pharmacy Until Its Complete Detachment from Medicine."

Prof. S. Bodenheimer also spoke on "Yehudah Abarbanel, Who United Italian Humanism with Jewish Tradition." Other lecturers at the congress included Dr. A. Goldstein "The Doctor in Our Ancient Literature," Dr. I. Seide "Medicine and the Natural Sciences in the Travels of Benjamin of Tudela," Dr. I. Leibowitz "Avraham Ibn Ezra's Book of Experiments," *Dr. Isaiah Leibowitz "The Problem of the Eternity of the Universe in the History of Scientific Thought,"* Dr. D. Margalith "Anatomy and Surgery in the Talmud," Dr. Z. Plashkes "Medical Historians of the Viennese School," and Prof. I. Calugai "Dates in the History of Chemistry Up to 1952."

Social Aspect of Food Rationing.—In a recent review on nutrition, Dr. K. Guggenheim, a lecturer at the Hebrew University, mentioned that for some time the influence of the austerity program on nutritional conditions of the population has been the source of grave concern in many responsible quarters. Therefore, interested circles looked forward expectantly to the report "Level of Nutrition in Israel, 1951," published by the Central Bureau of Statistics and Economic Research.

The 1,002 families investigated in the spring of 1951 represented a true cross section of the whole wage earning population. The statistical material on food consumption was submitted for analysis to Dr. Sara Bavly, head of the institute for Nutritional Guidance of the Ministry of Commerce and Industry. The main question to be answered was whether the nutritional status has been improved or worsened in recent years. Answering this question, Dr. Bavly compared her data collected in 1952 with those obtained in previous surveys. This comparison shows: (1) a steady increase in the consumption of milk and milk products, fruits, vegetables, and bread; (2) a fairly constant consumption of sugar, fat, and of meat and fish; and (3) low consumption of eggs in 1948 and 1950 and return in 1951 nearly to prewar level. Changes in the supply situation have created a shift within some of the major food groups. Israel is now eating more fish and less meat, more egg powder and fewer fresh eggs, more skim milk powder products, and more margarine and less butter than they did some years ago.

But the most important changes happened within the different economic groups. The consumption of milk and milk products in the higher economic groups rose by 43%, whereas that of eggs, and meat and fish, decreased by 31 and 54%, respectively. In the lower economic groups, however, the consumption of milk and milk products and of eggs increased by 127 and 24%, and that of meat and fish decreased by 38%. In 1946 well-to-do persons consumed 119% more milk and milk products, 141% more eggs, and 128% more meat and fish than those less prosperous. In 1951 the consumption of milk and milk products, eggs, and meat and fish by the highest economic group surpassed that of the lowest group by 35, 35, and 69%, respectively. This improvement of social justice in food distribution, accomplished by leveling out the extremes in consumption at both ends of the scale, is the result of the nutrition policy of the government (controlled distribution of essential foods, price control, subsidies for some basic foods, and special rations for pregnant women and children). This is one of the greatest achievements of the state and constitutes one of the major factors contributing to the improved health situation.

Two years have passed since the survey was conducted. The economic situation has worsened, the real income has decreased, and many thousands of wage-earners are unemployed. Since a survey of a large representative sample of the whole population cannot be carried out at short intervals, one has to rely on government statistics of the amounts of food that is marketed monthly. These monthly statistics include not only the food that goes through the usual channels to the average consumer but also the special rations for pregnant women, children, heavy workers, and sick persons, as well as the food delivered to restaurants, hotels, hospitals, institutions, and the army. The total of this amount of food divided by the total population indicates the per capita figure of marketed food. It is to be noted, however, that marketing figures may tend to underestimate somewhat the real consumption, because a part of the food consumed is derived from external sources. Assuming a more or less constant relation between marketing figures and real consumption, certain conclusions as to the present nutritional situation may be drawn after studying the following table, which summarizes the major food groups in grams per capita per day.

Food Groups	Consumption, Spring, 1951	Food Quantity, Spring, 1951	Food Marketed, 1952
Milk and milk products (milk equivalents)..	483	411	303
Eggs (fresh)................................	35	33	25
Meat and chicken (without bones)..........	20	26	12
Fish (without bones).........................	40	32	34
Bread, flour, legumes........................	344	388	403
Fats and oils................................	30	32	40
Sugar (including jam and sweets)..........	42	47	55
Fruits	484	308	248
Vegetables and potatoes.....................	256	280	372

This table shows a marked increase in the amounts of bread, fats, sugar, and vegetables marketed in 1952 above the figures for spring, 1951, and a considerable decrease in milk, eggs, meat, and fruits. These changes may partly be due to seasonal variations (increased production of milk, eggs, and citrus fruits in February and March); the increase in the marketing of bread may point to an increase in waste and its use as chicken feed; and the highly increased amounts of vegetables during 1952 are the result of the bumper crop of last year. But the most important feature of the change in 1952 is the considerable decrease in the supply of milk, eggs, and meat. In terms of nutrients, the supply of calories, iron, and vitamins may not have significantly changed during 1952, but the situation concerning animal protein and calcium is now worse. It is, therefore, most important to increase the milk consumption to the level reached two years ago, since milk and its products are the cheapest source of animal protein.

Public Health Courses.—Practical courses in public health, the newest branch of medical science, are to begin at the Hebrew University-Hadassah Medical School in the coming academic year. This was announced recently by Dr. K. Mann, director-general of Hadassah in Israel. Studies will be conducted at the local Hadassah medical center set up last January at Beth Mazmil, west of Jerusalem, not far from the site where the future Hadassah medical school will be erected. Education in public health is not limited to the diagnosis and treatment of disease but also considers the influence of the family background and the entire environment, together with its cultural, social, and psychological problems. Medical students who, within the framework of their studies, are to go out to work in the villages will study for two months at Beth Mazmil and will be engaged for another two months in practical work. After receiving their diplomas, they will each be responsible for the inhabitants, both sick and healthy, of 40 houses.

A staff consisting of a physician, two nurses, a social worker, and a health instructor has been appointed for every 200 families. The duties of the staff, besides individually treating every patient applying to them, concern caring for the state of health in families and in the general neighborhood and studying nutrition. Routine medical and physical examinations are given to all the inhabitants even when they are apparently healthy. The important point is that the same physician and the same nurse attend not only the same patient but his entire family. In cases of need, the entire Hadassah machinery is at the disposal of the inhabitants, and specialists visit the area at regular intervals to receive patients.

In addition, a 10 dönüm playing field and a club are to be established, as a means of developing health. There is close cooperation between the local council of the quarter, the Ministry of Welfare, and local schools. The medical center will also serve as an important place of research in the field of social sciences and psychology.

LONDON

Antibiotics and Whooping Cough.—The Whooping Cough Subcommittee of the Antibiotics Clinical Trials (Nontuberculous Conditions) Committee of the Medical Research Council has just published its report on the treatment of whooping cough with antibiotics (*Lancet* 1:1109 [June 6] 1953). It is based on the findings in 294 children, aged 0 to 5 years, admitted to hospital with uncomplicated clinical cases of whooping cough within 21 days after the onset of the earliest symptoms. Chloramphenicol was administered to 98 children, aureomycin to 96 children, and a mixture of lactose and quinine to 100 children (the control group). The drugs were all dispensed in cachets. The dosage schedule was as follows: aged 0 to 11 months, 1 gm. daily; aged 12 to 25 months, 1.5 gm. daily; aged 36 to 59 months, 2 gm. daily. The drugs were given twice daily in equally divided doses for the first seven days of the observation period. Each child was observed for 20 days. As the results with chloramphenicol and aureomycin were comparable, the two groups were combined and are referred to as the "treated group," except for consideration of complications and deaths. For analysis, cases were subdivided into early cases, symptoms for 1 to 8 days before treatment; intermediate cases, symptoms for 9 to 15 days before treatment; and late cases, symptoms for 16 to 21 days before treatment.

The average number of paroxysms per case per day was less at all stages in the treated than in the control group, but the difference was only statistically significant in the early cases, e. g., on the eighth day the average difference was 5.7 paroxysms (difference/standard error 3.2), whereas in the intermediate and late cases the difference was only 2 paroxysms in favor of the treated group. Again, in the case of the severity of the paroxysms the difference was most marked in the early cases, e. g., the proportion of early control cases in which the paroxysms were described as absent or mild increased from 22% in the first four day period to 29% in the fifth four day period, whereas in the treated cases the percentages increased from 17 to 66. The comment is made that "it appeared that the drugs influenced the severity of the paroxysms to a greater degree than they affected the number of paroxysms in the intermediate cases." On the 3rd and 8th days of observation, but not on the 1st, 2nd, and 11th days, the proportion of patients from whom Hemophilus pertussis was isolated was greater in the control group than in the treated group. During the observation period, 19 patients noted respiratory complications: 7 in the control group, 7 in the aureomycin group, and 5 in the chloramphenicol group. In addition, there were three fatalities: a 6-week-old infant died of bronchopneumonia in the control group, and a 7-month-old infant in the aureomycin group died in convulsions. In a 1-year-old child in the chloramphenicol group widespread collapse of the lungs developed, which proved fatal. None of the complicated or fatal cases occurred in patients treated within eight days of the onset of symptoms. Presumed toxic effects were noted in 28 cases: vomiting 19 (7 on chloramphenicol, 11 on aureomycin, and

1 control); anorexia 5 (3 on chloramphenicol and 2 on aureomycin); diarrhea 2 (both on chloramphenicol); redness of buttocks 1 (on aureomycin); urticarial rash 1 (on aureomycin).

The conclusion finally reached is that "the present study suggests that early recognition and early antibiotic therapy of whooping-cough may help to reduce the severity of the infection, but that little is gained from antibiotic treatment of cases in which even slight symptoms have been present for more than a week."

Cruelty to Children.—Under this title the Association of Children's Officers has just published a memorandum, which it has prepared in response to a request from a Joint Committee of the British Medical Association and the Magistrates' Association. This is an able review of a difficult and increasingly important problem. In reviewing the use made of the law in these cases, the association feels that the law might be used with greater flexibility. It deprecates the "present practice of almost automatically committing children to the care of the Local Authority, whenever an offence has been proved." It also considers that the parents convicted of a first offense, especially neglect, "might more often be given a severe warning that another conviction will result in a sharp term of imprisonment and then be sent home with their children on probation to try to do better in the future." An appeal is made for a wider use of the provision for placing children under supervision at home and for taking recognizances from parents. "If the parents have behaved so badly that the children are taken away, especially if the offence has been repeated, the parents should be required to make a very substantial contribution to their maintenance." One child under institutional care for 15 years may cost £3,000, and a single large family may cost well into five figures. "At present, many convicted parents are better off financially (and better off than their law-abiding neighbors) without their children than with them."

On the general question of remedies, the memorandum states that "a substantial reduction of ill-treatment and neglect can only be achieved by measures to promote an improvement in the spiritual state of the nation." The machinery for detecting and combating physical violence is considered to be adequate, and no extension of powers to enter private houses is required. The prevention of mental ill-treatment is "a much wider problem, and one on which a lead can only be given by the medical profession." The final conclusions of the memorandum may be axiomatic, but they are worth quoting as an admirably concise summary of a problem that is worrying Western civilization to an increasing extent:

"(a) The family (even when it consists of mother and child only) must be treated as a living organism and not split up into smaller units for the purpose of social action.

(b) There is no perfect substitute for the natural father and mother.

(c) The child has spiritual, mental and emotional needs, as well as physical ones.

(d) There is need for amendment of the law relating to parental responsibility.

(e) The removal of a child from his home is a dangerous and costly expedient which should only be resorted to after all other means of ameliorating his hardships have failed. The courts should insist upon the most exhaustive enquiries before removing a child from his parents."

Lind Bicentenary.—The University of Edinburgh has been paying due respect to one of its greatest medical sons by celebrating the bicentenary of the publication of James Lind's classical "Treatise on Scurvy." The celebrations included a symposium organized by the Nutrition Society, the participants in which included Dame Harriette Chick, Prof. H. A. Krebs, and Sir Edward Mellanby from Great Britain, Drs. R. M. Kark, C. G. King, and V. P. P. Sydenstricker from the United States, Prof. E. J. Bigwood from Belgium, Dr. H. Grounelle from France, and Dr. M. van Eckelen from Holland. The more formal part of the celebrations included the bestowing of the honorary degree of LL.D. on Surgeon Vice-Admiral Sir Sheldon Dudley, F.R.S., the distinguished holder of the office of medical director-general of the Royal Navy during the greater part of World War II, who also delivered the Lind oration, and a reception by the president of the Royal College of Physicians of Edinburgh. The concluding event was a dinner in which the menu consisted of foods especially rich in vitamin C, including scurvy grass as a garnish, adrenal capsules dressed with paprika, and parsley as a savory.

Addition to the Royal College of Surgeons.—In spite of her crowded program, Queen Elizabeth found time before her coronation to lay the memorial stone commemorating the extensions, which are creating such a metamorphosis in the buildings of the Royal College of Surgeons in Lincoln's Inn Fields. The occasion was a memorable one, carried out with all the pomp and colorful tradition of which the Royal Colleges can boast. A large number of the college buildings were destroyed in an air raid in 1941. The current building program is devised to make good the wartime losses and to extend the college. The work of rebuilding is being carried out in three phases, the first of which was the one commemorated by the visit of the Queen. Its major item is the building of the Great Hall, which will seat 700 persons. The heaviest loss the college sustained was the Museum, which lost three-fifths of its buildings and contents. As a result of a gift of £100,000 from the Wellcome Trustees, it is planned to erect three floors of museums above the Great Hall, each complete with exhibition rooms and workrooms. In line with these museums will be three floors of laboratories. Centrally placed in the college will be an extension of the Library, and connecting the old and new buildings will be the Exhibition Hall, where there will be facilities for the display of works of art, documents of interest, and other treasures of the college. The second phase of building will include the Nuffield College of Surgical Sciences, a residential college for postgraduate students, which will provide bedroom and full collegiate facilities for 90 students. It is named after Viscount Nuffield who has contributed £250,000 toward its cost. Above Nuffield College will be a department of anesthesia. The third phase of building will consist of the reconstruction of the southwestern part of the existing college, including the provision of a Fellows' Common Room. The whole, when completed, will constitute a noble and worthy home for English surgery. There are many who hope that it may even be a step toward the establishment of an Academy of Medicine representing all branches of British medicine and including all the Royal Colleges.

Responsibilities of General Practitioners.—In a foreward to the coronation issue of the *Practitioner* (June, 1953), which is devoted primarily to a symposium on "General Practice: Today and Tomorrow," the Minister of Health emphasizes the important role of the general practitioner. "The status of the general practitioner," he says, "depends essentially upon three things: the trust of his patients, the respect of his colleagues, and the means to do his job adequately. In the last resort all these depend on him but there is much that others can do to make them manifest and to help him in his arduous and responsible work. The hospital service can do much to help," and the minister emphasizes here that "the general practitioner has a right to expect to be treated as a colleague and an equal, an essential member of the team. He should have direct access to x-ray and pathological services for his patients, [and] he should also be made welcome in the hospital if he cares to accompany or visit his patient or to come on a consultant's round." The general practitioner, too, has his part to play by keeping up-to-date and ensuring that "the environment in which he sees his patients—his surgery, his waiting room and his equipment—are such as to inspire respect and confidence." The aim must be to break down the attitude that only in hospitals can the best treatment be obtained, "for there are many patients for whom hospital care is wrong and that of their own doctor right."

In thus epitomizing, in characteristically concise terms, the vital importance of an efficient general practitioner service the Minister has struck a note that badly required to be sounded. Far too many patients are being sent to hospitals, particularly as outpatients, who could be dealt with much more effectively by general practitioners. Now that conditions of service have been improved, it is to be hoped that general practitioners will be able to reorganize their practices so that they can once again become family physicians, and not merely the "clearing-house clerks" for a hospital that they have tended to become during these hectic and confused early years of the National Health Service. What is probably now required is some education of the public as to when, and when not, to consult their physicians.

MEXICO

Incidence of Primary Carcinoma of the Liver.—The high incidence of primary carcinoma of the liver in certain races or peoples (such as the Chinese and Bantus) and its association with liver cirrhosis, especially of the postnecrotic type, and probably with malnutrition, has been described by several investigators. In Mexico, where both liver cirrhosis and malnutrition are frequent, there had previously been no studies on the incidence of primary carcinoma. With the aim of obtaining definitive data about this problem, Drs. Sepúlveda, Rivera, and Rojas analyzed the reports of autopsies performed in the Hospital de Enfermedades de la Nutrición (Mexico City) from 1947 to 1951. Their results were published in the *Gaceta Médica de México* (84:147, 1952).

In the 500 autopsies 5 cases of primary carcinoma of the liver and 46 of secondary carcinoma were found. This would apparently give a very high incidence (1%) of carcinoma of the liver, but such a figure is not a true representation. The Hospital de Enfermedades de la Nutrición has a high proportion of patients with liver diseases, as is demonstrated by the fact that in more than a third of the cases in which autopsy was done the main disease was in the liver. Thus in 1,047 autopsies in the Instituto Nacional de Cardiología, where another type of disease is predominant, not a single case of carcinoma of the liver was found. Similar results were obtained by review of 93 autopsy protocols of the Hospital Militar (Military Hospital).

The authors point out the following etiological factors that should be considered: 1. Preexisting cirrhosis, mostly of the postnecrotic type, with its tendency toward cell regeneration progressing to an anarchic extreme due to unknown causes, would finally produce carcinoma. In four of the five cases studied, the association of carcinoma with postnecrotic cirrhosis was found. 2. Heredity may be a factor, since the authors observed primary carcinoma of the liver in two brothers. These two men are not included in this series, because they were private patients in whom autopsy was not performed. The diagnosis, however, was confirmed by biopsy. A past history of malnutrition or parasitosis of the liver was not found in the cases studied.

From the histological standpoint, four of the carcinomas were of the multiple nodule type and one was a cystadenocarcinoma. Microscopically three were classified as liver cell carcinomas, one as a cholangiocellular carcinoma, and one as a cystadenocarcinoma.

The average age of the patients was 46 years. It was pointed out, however, that the disease is found in persons of all ages; in the Hospital Infantil de México (Children's Hospital), two cases have been found in 691 autopsies, an incidence of approximately 0.3%. (The children were 17 months and 5 years old; associated cirrhosis was not found in these cases.) Three of the five patients studied were men and two were women.

The most frequent clinical pictures were (*a*) appearance of systemic symptoms and at the same time symptoms of a tumor of the liver in previously well persons and (*b*) the appearance of pain in the hepatic region, enlargement of the liver, and a rapidly unfavorable course in persons with cirrhosis.

The liver function tests showed dysfunction in all cases and generally revealed progressive and severe liver insufficiency. The sulfobromophthalein (Bromsulphalein) retention and the direct serum bilirubin tests were especially sensitive. In two cases a high alkaline phosphatase level was found. Although these findings are not specific and may be found in other diseases of the liver or the biliary tract, it is commonly accepted that carcinoma of the liver does not cause marked alteration in the liver function tests. The experience of the authors does not confirm this impression; on the contrary, as a rule, marked and progressive dysfunction was found.

The only way of making a positive diagnosis during the life of the patient is by laparotomy, since it permits a macroscopic inspection of the gland, a specimen of the tumor may be secured, and control of any possible hemorrhage is easy. Moreover, if the pathological diagnosis is made immediately and the neoplastic lesion can be excised, a radical operation may be carried out at the same time.

Liver carcinoma can be confused with cirrhosis, mainly of the postnecrotic type, and with secondary carcinoma of the liver. Less frequently it is confused with amebic abscess. The disease leads rapidly to death; the average survival in the authors' cases was six months after initiation of symptoms. Death was due to hepatic coma in four cases and in the other to cachexia due to cancer.

New University.—Until 12 years ago the subtropical state of Morelos had no institution of higher learning. At that time with economic conditions improving steadily, the Instituto Superior (a college with some but not all professional schools), was founded at the resort town of Cuernavaca, the state capital. Since then the quality of its studies has been improved and the number of students increased, paralleling the growth of the general population of the state.

Several months ago works were undertaken to transform the Instituto Superior into a university. Since every university is required to have a school of medicine, this new one will be the 14th in Mexico. The establishment of the new university was marked by a solemn ceremony at Cuernavaca on May 3, which was attended by representatives of other universities.

New Study Plan.—Many Latin American universities have been financially unable to carry out expansion programs commensurate with the rapidly increasing number of students applying for matriculation in the professional courses. The problem of heavily overcrowded classes, which tend to lower the professional quality of the graduate, must be especially guarded against in the faculties of medicine.

To combat this dangerous problem, a new study plan, adopted six years ago by the Faculty of Medicine of the University of Guadalajara, has proved a practical and efficient means of assuring the high quality of the graduate student and of maintaining or improving the desired standards of the medical profession despite limited physical and economic resources. As a result of the success of this plan, it is being studied for use in other Mexican and Latin American universities.

After careful studies of the curriculums of large and small universities in the United States, Canada, and Europe, the plan now in effect was adapted to conform to the physical and economic conditions of the Faculty of Medicine of this university. These considerations led to the decision to limit the first year matriculation to 75 students, 50 of these to be selected from among the graduates of the medical preparatory school of Guadalajara, 20 from other similar Mexican institutions, and 5 from foreign preparatory schools.

From these groups approximately 125 students with the highest scholastic rating are selected upon graduation from preparatory school. These students then undergo three examinations: (1) complete physical examination; (2) academic examination of three or more of the basic preparatory subjects; and (3) vocational aptitude examination, including psychological study.

The curriculum consists of four academic years and two years of practical work, which includes the study in the specialties, clinical work, and six months of social service. At the end of the six year period, the student's qualifications for a degree are further judged on the basis of the results of a final academic examination, a clinical examination, and the presentation of a thesis. Upon successfully passing these examinations, the student is given his diploma and doctorate, which officially entitles him to practice medicine. The practical results of this plan have proved especially gratifying in the clinic, where small, rotating groups of from 8 to 10 students readily demonstrate their careful preparation and a thorough comprehension of the basic studies.

CORRESPONDENCE

FOREIGN-TRAINED PHYSICIANS

To the Editor:—We are writing to applaud the statistical data on "Licensure of Foreign-Trained Physicians" in THE JOURNAL May 30, 1953 (p. 438). We wish, however, to stress the growing problem of what is to be done with the increasing number of graduates from unapproved foreign medical schools. Our organization, the National Committee for Resettlement of Foreign Physicians, has, since 1939, concerned itself with the equitable resettlement of qualified foreign physicians who are refugees from persecution abroad. Since the early days of Hitler, there has been a steady immigration of foreign physicians (except during the United States' participation in World War II) from many parts of the world. Our agency is the only one in the United States that is concerned with the resettlement problems of these immigrants. Between 1939 and 1942 we registered and rendered service to about 7,000 emigrant physicians, mostly from Germany and Austria. After World War II, a new wave of immigration began and consisted more and more of displaced persons and refugees from behind the Iron Curtain, the Near East, India, and China where conditions forced emigration.

We think that American physicians can point with pride to the prodigious achievement in the successful assimilation of more than 10,000 such immigrants in the past 15 years. Nowhere in the world has the immigrant physician been received or accepted on such a scale or with such friendship, even though many states raised barriers to their licensure when very large numbers came in a short period. Our committee believes firmly in tests of qualification designed to find the fit immigrant physician who can be of service to our people, especially in understaffed communities or the armed forces and, thus, add substantial numbers to our medical manpower. Screening to exclude subversives, evaluation of language and scientific aptitude, and securing first citizenship papers are desirable goals that we try to fulfill in giving advice and guidance.

Our committee receives dozens of requests each month for the services of well-trained foreign physicians to fill posts as interns, residents, admitting physicians, anaesthetists, and staff physicians in state hospitals for mental disease or treatment of tuberculosis. Our experience with foreign physicians indicates that they need a period of rehabilitation in American hospitals so they may learn American ways, improve their English, and find opportunity to fit into the community. It is heartening to see that 45 state boards now permit foreign-trained physicians to be examined under varying conditions. We believe that the requirement of full citizenship now demanded by 26 of the boards merely delays the resettlement of otherwise qualified persons for five years before they can apply for licensure in these states. This requirement penalizes both the needy community and the physician seeking to fill an empty post. The requirement that applicants file their intention to become citizens is reasonable, and the successful applicant with first papers should be issued his license with the understanding that he must complete his naturalization within five to seven years after issuance of his first papers.

Our committee is increasingly concerned about immigrants who are graduates of foreign medical schools that are not approved by the Council on Medical Education and Hospitals and the Executive Council of the Association of American Medical Colleges. There are hundreds of these graduates in the United States; some succeed in gaining admission to some state boards; others are barred, apparently permanently, and must seek institutional posts if they are to remain active in the medical profession. We believe that the recent ruling by the board of regents in New York State, requiring refresher courses in the basic and clinical sciences, is a reasonable step designed to add to the qualifications of such physicians and to test the candidates in this group. Such a course is now offered by the New York University-Post Graduate Medical School, and we are happy to report that during the first year those who were recommended for admission to the state licensing board by New York University did better on all examinations as a group than all other foreign candidates. If other medical schools with equal facilities would offer a similar course, the means would be provided for making better use of immigrant graduates of unapproved foreign medical schools. Since these persons are immigrants who have entered the United States legally, we believe that everything possible should be done to facilitate their assimilation in the medical profession, thus ensuring equal treatment as potential citizens of the United States. Theirs is a peculiar plight. They are the victims of their fate, not the architects. If they are not permitted to take licensing examinations, then both the competent and the incompetent are excluded without a test. With the present shortage of young physicians for institutional jobs, many of these persons are now in such posts, and many may be expected to continue to work as unlicensed, unregistered physicians in hospitals that cannot get fully qualified or certified persons. For these reasons, we believe that steps should be taken by state boards and medical schools to facilitate the retraining or the additional training of such persons in order to find the qualified among them and to exclude the unqualified.

PLIGHT OF THE HOSPITAL

To the Editor:—To a degree the development of hospitals has paralleled the advance of civilization as a whole. First there was the provision of the bare necessities of existence. Then slowly the scientific aids and the comforts, which made life worth living but more expensive, were added and were followed by the need to conserve those advantages for those most in need of them. Many sciences have combined to evolve the modern hospital equipped with every device known to the healing arts and staffed with a wide variety of skilled workers. Drawn by such manifold advantages, growing numbers of persons go to the hospital confident that there they will receive the benefits that the experience of others has led them to expect.

Today, however, the demand for this high-geared and complicated service surpasses the supply of both facilities and personnel. If relief is not found soon, there will inevitably be congestion and delays and the threat of lower standards. The situation may be compared to opening all the water faucets in the hospital at one time. Pressure would drop to a trickle or fail completely and slow down all functions dependent on this vital element until the load was reduced to normal. In hospitals the problem is now one of control and of equalizing the load by avoiding unnecessary peaks and by eliminating all demands not indicated by calm professional judgment and an understanding of the problem of supply and distribution. Any past emphasis on luxury and convenience that has induced people to use modern hospitals must yield to priority based on medical necessity wherever facilities and services are overtaxed or understaffed.

Who is to control the demand and avert a possible crisis? It is not the management, which is busy supplying steam and plugging the leaks, or the public, which clamors for the scarce accommodations and skilled service. It is the author of the advances in medicine that require new gadgets and expensive technical help to operate them; it is the person who prescribes their use on his patients—the physician.

Every admission and discharge, every day's stay in the hospital, every medication or special diet given, and every procedure carried out during hospitalization is by order of the physician. His hand is on the spigot, and it is mainly to him that we must look for the conservation and the quality of what flows out of it. He, more than anyone else, can and must help by limiting to real necessities the resulting costs that inevitably find their way into a hospital's budget and then to the patient's bill. Since the so-called "ancillary services," all of which are rendered only on the physician's order, may account for 50% of all charges to patients, their effect on the cost of hospital care and the imperative need of conservation in their use are obvious. Hospital charges are based essentially on the total cost of operation divided by the units of service actually rendered. The nature of a hospital's work is such that the major part of its expense is fixed and economical operation thus depends on high utilization of facilities and services. As the stand-by cost of a hospital bed varies little whether it is empty or occupied, cooperation of the physician by scheduling admissions when beds are available and by giving advance notice of his discharges can be the most potent factor in stabilizing and controlling basic costs, as well as in increasing a hospital's capacity to serve both the public and the medical staff.

The health of the nation and the livelihood of the physician depend increasingly on the adequacy, efficiency, and solvency of hospitals. True, hospitals are prepared to deal with crises when they occur, but, to meet them, hospitals must have periods of rest and assurance of support, both internal and external, both material and spiritual, so they can replenish the vitality expended during their periods of strain and strengthen their appeal to urgently needed workers. At the 102nd annual meeting of the American Medical Association, Dr. P. D. White stated that the serious degrees of heart disease can be postponed, or even prevented, by the adoption of common sense measures, such as "avoidance of prolonged nervous tension and excessive overweight." Our hospitals will survive if an informed public and a considerate medical profession prescribe similar measures for the hospitals and see that they are scrupulously carried out.

MECONIUM ILEUS

To the Editor:—I enjoyed the article "Meconium Ileus" by W. Foster Montgomery in The Journal (152:225 [May 16] 1953). Recently I had the opportunity to observe a similar case, and, although the patient eventually died because of the disease, two observations were made that may be of significance: (1) human bile, containing pancreatic juice, obtained from an adult with an indwelling T tube in the common bile duct, proved to be a very effective substance for irrigating the distal ileum and colon and (2) evidence suggested a definite defect in peristalsis that was characterized by active segmentation and reversed peristalsis but an inadequate forward propulsive peristaltic wave. If these observations are correct, the peculiar nature of the obstruction and the peculiar character of the inspissated meconium could reasonably be explained on this basis alone.

The patient was a 48-hour-old baby girl in whom, shortly after birth, all the signs and symptoms of small bowel obstruction developed. The diagnosis of meconium ileus involving the entire colon and over 75% of the terminal ileum was confirmed at operation. The narrow ileum and colon were approximately 5 mm. in diameter and contained typical, thick, tenacious, "bubble-gum-like" material. The bowel above this point showed progressive and tremendous dilatation. Because of the extent of disease, anastomosis or resection of the involved portion of the ileum and colon seemed unfeasible; therefore, a double-barreled ileostomy was performed in the hope that anastomosis or resection could be performed at a later date. During the postoperative period, both loops of the ileum and rectum were irrigated with bile obtained from the T tube of an adult who had recently undergone gallbladder surgery. Laboratory examination of the bile confirmed the presence of strong concentrations of pancreatic secretions. Irrigation of the loops with this material resulted in prompt digestion of the inspissated meconium. The intestinal material assumed a more normal and soft character; but, in spite of this, there was inadequate drainage through the ileostomy even though the stoma was patent and easily admitted the little finger. Repeated observations of the abdominal wall revealed marked peristaltic activity at all times, but the proximal ileum and jejunum remained distended up to a point a short distance from the ileostomy. Passage of a catheter immediately deflated the dilated loop of bowel. It was thought that even though peristaltic segmentation was present, the intestine lacked the ability to propel the intestinal material in a forward, or downward, direction. The baby's condition improved somewhat during the first week or 10 days after surgery but then gradually deteriorated. The infant died one month after surgery, probably from inadequate nutrition.

Because this condition is rare, no one has been able to accumulate a series of cases large enough to make adequate experimental studies. The relationship between meconium ileus and pancreatic insufficiency is well known; therefore, the use of whole bile containing pancreatic juice from a patient with a T tube in the common duct seems theoretically sound and in this case proved very effective in producing digestion of the inspissated meconium. Abnormalities in the parasympathetic or autonomic nervous system, such as an absence of the myenteric plexus in the ileum and an imbalance in the nervous control of the pancreatic secretions, have been described. As far as I can determine, the possibility that these infants have rather active peristaltic segmentation and reverse peristalsis but not adequate forward peristaltic action is a new one that deserves further thought and consideration.

REPRINTS

To the Editor:—Through the facilities of The Journal I would like to present the following suggestions to publishers of all medical journals. Physicians interested in the development of a reprint file have found it rather difficult, in the cases of most journals, to contact the author of a particular article. This situation could be alleviated by including the address of the author either as part of the by-line or at the end of the article. A second suggestion is in connection with a better documentation of articles appearing in medical journals. Physicians who do not desire to keep a complete journal remove certain pages for filing. It is this group who would find it exceedingly helpful if the name, date, and volume number were part of the running head on each page. Some journals, such as the Journal of the American Medical Association, follow this practice, while others carry only the title of the article or the name of the author. For those who follow the literature closely and endeavor to keep current, these minor changes would save a great deal of time.

Oak Ridge National Laboratory
Post Office Box P, Oak Ridge, Tenn.

PROTEUS MIRABILIS

To the Editor:—The Proteus mirabilis has been recognized generally as a harmless strain. Some time ago, however, we performed a search for all the aerobic enteric bacteria strains found in the stools of sick infants under one year of age, who had diarrhea. In over 40 patients, each examined several times during the illness, the strain found was *Proteus mirabilis.* Recently, we suspected subacute bacterial endocarditis in a 70-year-old woman. Cultures from her blood, urine, and feces showed that P. mirabilis was present. No other strains were found. We believe, that this strain was the cause of the death of the woman.

COUNCIL ON INDUSTRIAL HEALTH

This statement is a revision of similar material presented at the Conference on Preventive Medicine held in Colorado Springs in November, 1952, and has been prepared for publication at the request of the Council on Industrial Health.

C. M. PETERSON, M.D., *Secretary.*

THE NEED TO TEACH INDUSTRIAL HEALTH TO MEDICAL STUDENTS

Robert A. Kehoe, M.D., Cincinnati

There is an acute and constantly increasing need for more and better medical performance in American industry, with particular reference to the application of practical measures of preventive medicine. This need is greatest in small industrial plants. A great opportunity is now open to the medical profession, in that almost any contribution made by it toward the solution of the obvious hygienic problems of industry will greatly improve its performance and demonstrate its usefulness to society. This is even more significant because the employees of small industrial plants represent more than half of our total industrial population. Professional responsibility and prestige demand that the attention of physicians and medical educators be directed toward the problems of human health that derive from the most characteristic and insistent activity of modern life—technological industrial production. The productive functioning of this segment of our population, impaired as it is by the inroads of preventable disability and absenteeism, is a matter of great economic and social importance.

In view of the dearth of trained personnel in industrial medicine and the certainty that most of the talent made available in the near future will be absorbed by large industrial organizations, the following facts are noteworthy:

1. Medical service in the small industrial organizations of the country will be provided by physicians engaged in general practice. 2. If such service is to include preventive measures to any extent, the practitioner of medicine will have to be familiar with the principles and techniques of preventive medicine as these apply to industrial employees and their environment.

It is not to be supposed that undergraduate instruction in preventive medicine in medical schools shall suddenly become a means of producing well-trained industrial physicians in large numbers or of converting practitioners of medicine into industrial physicians. This is neither necessary nor desirable. From time to time critics and enthusiasts have argued the urgency of modifying and expanding the undergraduate medical curriculum by the introduction of various types of highly specialized disciplines into the basic training of the physician. In general such proposals are opportunistic, illogical and naive; they are also unappealing to the educational profession, which, at its best, examines human and social requirements and values and undertakes to minister to them with an eye to history and human capacities and potentialities. What is urgently required is that the need for preventive medicine in an industrial society be recognized and presented to the student of medicine, that the opportunities for the exercise of the conventional skill of the physician in this direction be pointed out, and that the existence of a special field of practice, which requires specialized technical knowledge and skill, be made known. It is also important that a sufficient number of centers of medical education find means of making effective postgraduate training available for the physician who finds himself interested in or engaged in industrial medical practice along with general or specialized medical practice.

Instruction to undergraduates in preventive industrial medicine should be adapted intelligently to the needs of an industrial society by instructors who know the problems of industry. The means of teaching and the time at which it is done will depend upon the personnel and facilities available in the given medical school. The degree of emphasis should depend, to a reasonable extent, upon the comparative competence of the personnel and the facilities available for other types of instruction. In view of the need for effective instruction in occupational health, a responsible effort should be made in medical schools to provide adequate facilities and competent staff and to set aside some time for consideration of the principles involved. The relation of clinical medicine to occupational factors and disease must be taught, to be effective, in the clinical years of instruction. This can be done, when clinical material is available, by specialists in the field of occupational health who are also good clinical teachers, or it can be introduced into the general teaching of departmental clinicians who are familiar with industrial medical problems.

The principles and techniques of preventive medicine in industry in some medical schools, perhaps in most, may well be presented to the undergraduate medical student by the department of preventive medicine. Indeed, this seems the logical focal point for such instruction and for the catalysis of thought and planning necessary for the proper development of this subject in a medical center. The important asset here is a viewpoint toward preventive medicine. Beyond that, however, there is a mandatory requirement that persons be available who know the field of occupational health and are competent to practice in it. Otherwise there will be neither material for practical instruction nor an effective grasp of the methods through which pertinent principles are embodied into practice. Only rarely is the conventional teacher or department of preventive medicine found to be competent in this field. This basic requirement needs to be recognized, no matter what department is charged with final responsibility.

At the present stage of development, the nature and scope of instruction in its formal representation in the curriculum is relatively unimportant. What is important, as suggested previously, is a viewpoint and a steadfastness of purpose that will lead to the fulfillment of a professional responsibility. This responsibility can no longer be ignored by medical educators, if those so engaged hope to be regarded as responsive to their duty to society.

MEDICAL MOTION PICTURES

Surgical Repair of Direct Inguinal Hernia with Rectus Sheath Graft: 16 mm., color, silent, showing time 21 minutes. Produced in 1952 by and procurable on loan from Philip Thorek, M.D., 25 E. Washington St., Chicago 2.

This picture demonstrates in fine detail the technique for repair of a direct inguinal hernia utilizing a pedicled anterior rectus sheath graft, as described originally by Halsted. Numerous anatomic drawings have been used to amplify the already adequate operative sequences and descriptive titles. The operation itself is well presented, and all significant anatomy is adequately shown. The color photography is well done, and the titles are clear. The film can be recommended for surgeons, residents, and medical students.

Carcinoma of the Thyroid: 16 mm., color, sound, showing time 32 minutes. Prepared by R. Lee Clark Jr., M.D., University of Texas, Houston. Produced in 1951 by and procurable on loan from Davis & Geck, Inc., 57 Willoughby St., Brooklyn 1.

This film reveals a radical dissection of the thyroid gland and extensive block dissection of associated lymph nodes. The operation is performed on a malignant thyroid adenoma. The execution of the technique is good, the exposure adequate, and the extent of the procedure ample. In the beginning of the film, the part played by radioactive iodine is discussed. This is timely and worth while; however, there was no correlation between the subject matter being shown on the film and the discussion. This is not only annoying but confusing, since the theme of either one of the given subjects is lost. The photography is excellent. This picture can be recommended for surgeons, particularly those specializing in thyroid surgery.

BUREAU OF LEGAL MEDICINE AND LEGISLATION

MEDICOLEGAL ABSTRACTS

Hospitals in General: Board's Right to Dismiss Practitioner from Staff.—The plaintiff physician filed suit for an injunction to restrain the defendant hospital from depriving him of the use of the hospital facilities and for damages due to such denial. From a judgment against him, the plaintiff appealed to the Supreme Court of Iowa.

The Sisters of Mercy of Council Bluffs, Iowa, was organized and incorporated in 1938, as a nonpecuniary corporation under the laws of Iowa. It is a private corporation and, as such, operates hospitals, schools, and other institutions, one of them being the defendant, Mercy Hospital in Des Moines. The hospital is privately operated but is open to the public and serves all persons without regard to race or creed. The staff consists of two classes, associate and active. In the first-named class are the younger and the newer members, who, after three years, become eligible to be active members and officers. The officers constitute an executive committee to act as a board of directors to confer and advise, in matters pertaining to the welfare of the hospital, with the Sisters governing board, which is always present at the meetings of the executive committee or staff. Members of the medical staff of Mercy Hospital are required to be members in good standing of the corporate body known as the Des Moines Academy of Medicine and Polk County Medical Society and competent physicians of good character, who conduct themselves in accord with professional and ethical standards, are well recommended, and are endorsed by two members of the Polk County Medical Board, or of the staff.

The plaintiff, after graduation from Loyola University School of Medicine in Chicago, and after completing an internship in the defendant hospital, was issued a license to practice medicine in Iowa in 1933. Two years later he made written application to Mercy Hospital for appointment to the medical staff of the hospital and was accepted. At that time he was a member of the Polk County Medical Society. He remained a member of the medical staff of the hospital for 10 years, although he was not a member of the Polk County Medical Society after 1938, having been dropped in that year for nonpayment of dues. In 1945, the plaintiff's wife sued him for divorce, and during the divorce trial charges and countercharges relating to adultery and sexual promiscuities were made and there was a great deal of publicity in the local press relating to all the facts of the case. On Feb. 5, 1945, the plaintiff's wife was granted a divorce decree. The next day the executive committee of the medical staff of the defendant hospital met with the Sisters governing board, and a motion was made "that a recommendation to the Governing Board be made that Dr. P. F. Natale be dropped as a member of Mercy Hospital Staff and that he not be allowed to bring patients to Mercy Hospital." The motion was carried without a dissenting vote of the members of the executive staff or of the governing board. No other recorded action was taken by the Sisters governing board.

According to the by-laws of the medical staff, any member against whom any charges of unprofessional conduct or by-law violation have been preferred shall be notified of such charges and shall have the opportunity of appearing before the executive committee in his own defense before final action is taken. There is no evidence, said the Supreme Court, that any charge was preferred against the plaintiff. He was not notified of any charge. He was not present before the executive committee. He had no opportunity of appearing in his own defense before the committee before final action was taken, or at any other time. There were no witnesses before the committee or at the meeting. There was, in fact, no hearing. The knowledge of the committee was based only on rumors they had heard.

The decisive factor in this action, said the Supreme Court, is the fact that the Sisters of Mercy is a private corporation and has operated Mercy Hospital as a private business. The fact that its services and facilities are available to the public does not make it a public corporation, whether for pay or as charity. It is a fundamental and generally accepted rule that courts will not interfere with the internal management of a private corporation. In accordance with this rule the power to manage and control a hospital operated by a private corporation includes the authority and power to exclude physicians from the privilege of practicing their profession in the hospital. Thus, being a private corporation, the Sisters of Mercy had the right to make rules and regulations respecting patients and physicians, and to conduct the hospital as they saw fit, as long as its acts or omissions were not fraudulent, illegal, *ultra vires,* intentionally negligent, or otherwise wrongfully injurious to another. One requisite to membership on the hospital medical staff, the Supreme Court continued, was that a physician be a member in good standing of the Polk County Medical Society. The plaintiff was not a member of this society on Feb. 5, 1945, when the staff made its recommendation, or on March 6, 1945, when the governing board notified him of his dismissal, and had not been a member for over seven years. The fact that he had been permitted to practice as a member of the staff during such period would not stop the corporation from dismissing him. His permission to attend his patients in the hospital and use its facilities in his practice was but a privilege, and not a right vested in him by contract or other obligation of the Sisters of Mercy. Neither, said the Supreme Court, does the fact that no charge was preferred against him by the executive committee of the staff, or by any one else, and that no hearing was had before the committee, or opportunity given him to make a defense, avail him in this action. The by-laws containing these requirements were by-laws of the staff and were not binding on the governing board. The fact that the plaintiff was not a member of the county medical society was sufficient in itself to effect his dismissal from the staff, so that if he had been afforded full opportunity to make a defense, it would have been of no aid to him.

Another requirement for membership on the staff was good character and conduct in accord with generally accepted moral standards. It was for the Sisters of Mercy, as a private corporation, through the governing board of Mercy Hospital, to exercise its discretion and to decide whether, because of the evidence in the divorce trial and its extensive publicity, the plaintiff then qualified under this requirement.

The failure of the plaintiff to meet either of these requirements for eligibility to the medical staff of Mercy Hospital, concluded the Supreme Court, sustains the decree of the district court. Accordingly, the judgment in favor of the defendant hospital was affirmed. *Natale v. Sisters of Mercy of Council Bluffs et al., 52 N.W. (2d) 701 (Iowa, 1952).*

Placental Blood Serum in Treatment of Rheumatoid Arthritis.—Active rheumatoid arthritis in women often improves during pregnancy, and some investigators have used blood from pregnant or puerperal women or placental blood serum, in the treatment of rheumatoid arthritis. At Spielberg's clinic placental blood serum was used in 15 women, aged 26 to 29, with active rheumatoid arthritis. The serum was prepared as follows: Immediately after the birth of the baby, the umbilical cord was clamped and cut, and the placental blood was collected by letting it flow into the sterile collecting tubes of 60 ml. capacity. Stripping of the cord was avoided because this increased hemolysis. The amount of blood collected varied between 20 and 100 ml. and averaged about 40 ml. The blood was kept in a refrigerator overnight, and the supernatant serum was then pooled in a 500 ml. vacuum container. The pooled serum was centrifuged to remove red blood cells, and was Seitz-filtered and stored in the refrigerator. It was tested for sterility by aerobic and anaerobic culture, and a serologic test for syphilis was also done. The placental blood was not saved when the mother was Rh negative or had a history of syphilis, hepatitis, or jaundice. Different trial dosages, ranging from 5 ml. to 250 ml. and administered either intravenously or intramuscularly, revealed that optimal effects were obtained by giving 30 ml. intravenously daily for the first 14 days, 30 ml. three times a week for the next 2 weeks, then 30 ml. two times a week for 3 weeks, and finally 30 ml. once a week for one to three weeks. Placental blood serum produced a rapid, marked, and sustained improvement for six months in the systemic and local manifestations of rheumatoid arthritis in 10 of the 15 cases. The results were maintained without additional therapy, but further observation is required to determine the duration of this therapeutic result.

Survival of Human Red Cells After Storage.—Although blood plasma can be preserved for long periods by freeze drying, it has thus far been impossible to preserve red blood cells for more than 21 or 28 days. Brown and Hardin now describe a new technique that will preserve red cells for many months. In this process the red cells are first dehydrated with glycerin and then stored at subzero temperatures. Prior to transfusion they are rewarmed and the glycerin is removed. Over 90% of the red cells treated in this way were recovered intact after storage at -70 C for up to 6¼ months, and approximately 64% of these cells survived normally after transfusion. Only 79% of one lot of red cells stored at -15 C for 50 days were recovered intact, and 47% of these recovered cells survived normally after transfusion. No immediate or delayed reactions were encountered when these stored cells were transfused. There was evidence that a large portion of the abnormal post-transfusion loss of stored cells was due to the incomplete removal of glycerin from some of the cells before transfusion. Other possible methods for the more efficient removal of glycerin have been discussed. These studies, with those recently reported by British workers, indicate that the use of glycerin and subzero temperatures may eventually permit prolonged preservation of red blood cells for transfusion purposes.

Insidious Thrombosis of Aortic Bifurcation.—Until Leriche in 1940 aroused interest in thrombotic obliteration of the aortic bifurcation, this condition was regarded as rare. Now it is realized that thrombosis of the terminal aorta begins insidiously and progresses for a considerable time unnoticed, at first producing narrowing and only later a complete obliteration. Thirty-five such patients were seen at a Paris clinic for peripheral vascular diseases in the eight year period between 1944 and 1951. The cause of the aortic thrombosis was arteriosclerosis in 28 cases, inflammatory arteritis in 3, thromboangiitis obliterans in 2, syphilis in 1, and trauma in 1. While the cause of insidious thrombosis of the aortic bifurcation varies, the final pathological picture is similar in all cases: There is a complete obliteration of the aortic bifurcation. The thrombus begins in one of two places: in one common iliac artery, spreading upward toward the aortic bifurcation and then invading both the aorta and the opposite common iliac artery, or in the aorta below the point of origin of the inferior mesenteric artery, spreading downward. In resected specimens and necropsy material, the thrombus appears to originate in the common iliac artery three times as often as in the inferior mesenteric artery. The symptoms are fatigue, pain and weakness in the lower limbs, and impotence, all progressing slowly for months or years. Clinical and oscillometric studies reveal absence of arterial pulsation in both legs, but slight oscillometric pulsation at the upper end of the thigh may be present when the collateral circulation is well developed. Pallor of the lower extremities is often noticeable, even when the leg is dependent. Generalized wasting of the legs is difficult to detect, because it is symmetrical, but when questioned the patient often states that his legs are becoming thinner. When a patient complains of fatigue, pain, or coldness in his lower extremities or of impotence and the femoral pulses are absent, thrombosis of the aortic bifurcation should be suspected. Symptoms in insidious thrombosis never come on suddenly as they do in saddle embolus at the aortic bifurcation. Early diagnosis and treatment are important. The choice of treatment is between (1) bilateral lumbar sympathectomy with resection of the aortic bifurcation, (2) bilateral lumbar sympathectomy alone, and (3) resection and grafting of the thrombosed aortic bifurcation with or without lumbar sympathectomy. In this series of 35 cases 7 patients were first seen when advanced trophic changes in the lower limbs were already present and only one was benefited by treatment. Four of the 28 patients who were seen early refused treatment. Of the 24 who were surgically treated, 2 died, 3 remained unchanged, 16 improved, and 3 became symptom-free.

Resection and Homograft Replacement in Thrombosis at Aortic Bifurcation.—According to Oudot and Beaconsfield, the ideal treatment for thrombosis of the aortic bifurcation is replacement of the obliterated segment of the aorta by a homograft. They have used this treatment with encouraging results in five cases during the last two years. Once the diagnosis of thrombosis of the aortic bifurcation is made and confirmed by an aortogram, three points must be considered before grafting is decided upon: (a) the general condition of the patient, (b) the patency of the large arteries of the thigh and calf below the block, and (c) the preparation of the graft. Resection and grafting of the thrombosed aortic bifurcation is a long procedure, and may produce severe shock. Hence, careful evaluation of the cardiac and renal functions before the operation is essential. The homograft used is removed from a cadaver under aseptic conditions not later than four hours after death. All branching vessels of the removed aorta above its bifurcation are carefully ligated. The graft is then well washed to remove all blood and clots. After this, the graft is preserved at 4 C in an isotonic solution to which penicillin and streptomycin and 10% blood serum have been added. The graft is not used unless numerous cultures are sterile. The operative technique of the resection of the aorta and of the anastomosis of the graft is described and the histories of the five patients are presented. Symptomatically, they have all much improved. The toe skin temperature increased; arterial pulsation and oscillometric readings returned, although they were absent in the lower extremities before the operation.

Subendocardial Trauma Produced by Cardiac Catheterization.—The occurrence of subendocardial hemorrhage in a 39-year-old woman and right bundle branch block in a 59-year-old woman as a result of catheterization of the right side of the heart is reported. The first patient was catheterized for investigation of the hemodynamic changes incidental to the administration of high spinal anesthesia for cholecystectomy. On the first attempt to enter the tricuspid orifice, the tip of the catheter impinged high on the lateral wall of the right atrium. The patient died suddenly 28 hours after the cholecystectomy was terminated. At necropsy, death was attributed to atelectasis of the lungs. Petechial subintimal hemorrhages were observed in the right subclavian and innominate veins and in the superior vena cava; in the right atrium, on the anterolateral wall, there was a circular, solitary bright red subendocardial hemorrhage, which exactly matched in size the tip of the catheter used. In the second patient, on the first attempt to enter the pulmonary artery, the tip of the catheter impinged high against the medial aspect of the right ventricle. The catheter was withdrawn into the right atrium, and a 12 lead electrocardiogram was taken, showing a right bundle branch block. The subintimal and subendocardial hemorrhages described in the first patient were caused by trauma of the catheter. There was no known disturbance in the clotting mechanism of this patient. In the second patient, one may infer that a subendocardial hemorrhage in the region of the bundle of His may have been responsible for the right bundle branch block, which persisted for five days after catheterization. In neither patient was there evidence of heart disease. Subendocardial hemorrhages may occur as the result of cardiac catheterization, but they are probably uncommon and of importance only in that they may possibly be responsible for an occasional case of persistent conduction defect following cardiac catheterization.

Effects of HPC and Aspirin on Rheumatic Fever.—Of 68 patients with acute rheumatic fever, 34 were treated with probenecid (3-hydroxy-2-phenylcinchoninic acid) and the other 34 were treated with acetylsalicylic acid (aspirin). The total daily dose of probenecid was 20 mg. per kilogram of body weight. This total dose was divided into three equal doses and administered at hourly intervals. For the first 48 hours the total daily dose of acetylsalicylic acid was 1 grain (65 mg.) per 1 lb. (0.5 kg.) of body weight, with no total daily dose exceeding 150 grains (9.75 gm.). During the following five days the total daily dose was ⅔ grain per pound and for the following five weeks the dose was ½ grain per pound per day. The drug was given every 4 hours for the first 48 hours and every 6 hours thereafter. Both probenecid and acetylsalicylic acid were administered for a period of six weeks. Results showed that acetylsalicylic acid exerted a more favorable effect on the arthritis, fever, and erythrocyte sedimentation rate than probenecid. There was no difference between the two treated groups of patients in the course of acute carditis or in the incidence of significant murmurs 14 to 17 months after treatment was started. The duration of the acute illness appeared to be equal in the two groups. In the doses employed by the authors, acetylsalicylic acid appears to be preferable to probenecid in the treatment of acute rheumatic fever.

Comparison of Types of Cesarean Section.—Because he was not convinced that the low cervical cesarean section was a better or safer operation than the classical operation when both were undertaken in patients without gross infection, Falls started an experiment that took 26 years to complete. He operated upon a series of patients, alternating between the two operations. After 100 patients had been operated on, the results seemed so similar in the two series that it was decided that more operations would have to be done to make the figures statistically significant. He now is able to report on 500 operations. The conditions surrounding the operations were nearly identical. They were done by one surgeon unprejudiced in favor of either operation with sufficient experience in each operation before beginning this series to carry out the technique of both with equal facility. The operations were found to be equally difficult, and to produce approximately the same amount of postoperative morbidity, discomfort, and complications. In six out of seven patients who died, autopsy showed a normal postoperative uterus. These six cases showed disease probably incompatible with recovery whatever type of delivery had been used. In the remaining case a saprophytic infection of the uterus was noted, but the cause of death was given as postoperative pneumonia and secondary fibropurulent pneumococcic peritonitis. The common causes of death from cesarean section that could be attributed to the operation directly, such as shock, hemorrhage, anesthesia, or puerperal infection spreading from the operative site, were not seen in either series.

Acute Adrenal Cortical Failure as a Cause of Shock and Death.—In the first of the six cases described by Taylor and Essig, adrenal cortical insufficiency occurred when a masculinizing tumor of the adrenal cortex was surgically removed. During the postoperative period symptoms and laboratory evidence of adrenal cortical insufficiency appeared, and the patient died soon thereafter. Postmortem examination revealed atrophy of the remaining cortical adrenal tissue. The second patient had a course similar to that of the first following hysterectomy. This death was ascribed to the "hepatorenal syndrome"; however, further study convinced the authors that she died of adrenal cortical insufficiency. In the next two cases the adrenal cortical failure was associated with septicemia. A diagnosis of a Waterhouse-Friederichsen syndrome (adrenal cortical failure due to sepsis) was made. Both patients recovered in response to specific therapy. The eosinophil response to cortciotropin confirmed the diagnosis in one, and in the other the eosinophil count was suggestive of latent adrenal insufficiency. In the next patient shock developed 57 hours after hysterectomy. The signs and symptoms indicated acute adrenal cortical insufficiency. Treatment with adrenal cortical extract, cortisone, and desoxycorticosterone acetate produced recovery. A Thorn test for adrenal cortical insufficiency showed that this patient had impaired adrenal cortical function. The last patient had anterior pituitary cachexia, secondary to abruptio placentae and fibrinolysis. Adrenal cortical atrophy was demonstrated at autopsy; it was secondary to a lack of essential corticotropin stimulation from the anterior pituitary. The syndrome was recognized, but disagreement among consultants led to discontinuation of specific therapy; corticotropin and adrenal cortical substances should have been given. The authors feel that deaths from delayed postoperative shock hitherto ascribed to the "hepatorenal syndrome" or overwhelming sepsis may, in some instances, have been caused by unrecognized adrenal cortical insufficiency. Shock caused by adrenal cortical insufficiency should not be confused with shock due to hemorrhage, embolic disease, or atelectasis.

Is Elective Induction of Labor Justifiable?—It is Willson's impression that the mother and her child benefit less than the physician does by the unindicated induction of labor and that, aside from his convenience, little is accomplished by the procedure. At Temple University Hospital labor was induced in 180 of 9,667 deliveries (1.86%), but in only 50 was there no medical indication for the termination of pregnancy. The postpartum hemorrhage rate in induced labors was slightly higher than in spontaneous deliveries. The low fetal mortality in elective induction is to be expected, since the fetal loss at this stage of pregnancy is minimal under any circumstances. Analysis also proved that no more than 5 fetal deaths in full-term infants among a total of 9,667 deliveries might conceivably have been prevented by induction of labor. This suggests that it is seldom necessary. The author fears that approval by expert obstetricians, the supposed decrease in fetal mortality, and its convenience have led to the widespread use of induction of labor by physicians unqualified either to perform it or to manage the complications that might arise. He feels that rather than to approve the routine induction of labor in normal women because it does not add substantially to the risk for mother or child, the practice should be considered in the light of whether or not it is necessary. Although the increased emphasis on prenatal care and other worth-while aspects of obstetric practice has increased the demand on the physician's time, elective induction of labor will not solve this time problem. Since there is no proof that either fetal or maternal mortality is improved by induction of labor in normal pregnancy at term, Willson believes there is no justification for its use.

Tracheostomy in Postoperative and Post-Traumatic Care.—Many pulmonary complications will be prevented and lives will be saved if tracheostomy is done in patients with injuries to the trachea, bronchi, or chest, in patients who are unconscious or paralyzed, and in children following thoracic surgery. Incision in the midline exposes the tracheal fascia, and dissection of this fascia exposes the tracheal rings. The incision into the trachea should be made at least two or three rings below, never across, the cricoid cartilage. As soon as the opening has been made, a tracheostomy tube should be selected that is approximately one-half the diameter of the trachea. A small wick of gauze is placed along the tracheostomy tube to allow drainage from the tissues of the neck. A tight closure around the tracheostomy tube is not desirable, but two or three skin sutures are permissible if a long incision has been made. During the first few days the dressing should be changed daily. The inner cannula should be removed and cleaned every time the tracheostomy tube is aspirated. The cannula should not be left out of the tube except at the times of aspiration. The tube can be removed as soon as the reason for instituting the tracheostomy no longer exists. In chest injuries or after thoracoplasty, the tube should remain as long as paradoxical respiration is more than moderate; in unconscious or paralytic states, the tube should be left in place until the condition is relieved. Extreme care is necessary in removing tracheostomy tubes in patients who have bulbar poliomyelitis, particularly if there has been paralysis of the abductor laryngeal muscles. In many of these patients, permanent tracheostomies will be necessary.

Intestinal Obstruction Caused by Adhesions.—Of 81 cases of intestinal obstruction, exclusive of strangulated hernias, observed at the University of Oklahoma Hospitals, 47 were due to adhesions and adhesive bands. Parker describes the mechanism of obstruction produced by broad base adhesions and the treatment of such obstruction, pointing out that this type is usually responsive to intestinal intubation. A weighted tube, introduced into the small bowel, will relieve the open loop type of distention and, with subsidence of edema in the intestinal wall at the obstructed site, the acute occlusion is usually relieved. A two to four day trial of conservative therapy is justifiable in obstruction due to adhesions. Obstruction that occurs within the first three or four weeks following laparotomy should be treated by intubation, since the adhesions are pliable and stretching will relieve angulations of the bowel. The adhesive band, because of its strangulating capabilities, is much more dangerous than the broad-based adhesion. It may serve as a connecting band between two loops of intestine; between a loop of intestine and the abdominal wall; between the mesentery and a loop of intestine; or between two leaves of the mesentery. Adhesive bands produce obstruction by one of four methods. Differentiation between the strangulating and nonstrangulating types of intestinal obstruction is of vital importance. The onset of a strangulating obstruction is sudden. The pain is continuous and severe. Vomiting is usually of an intractable nature, and, because the closed loop does not permit the passage of sanguinous content, the vomitus does not contain blood. Abdominal tenderness is usually quite marked, and rebound tenderness is a valuable diagnostic sign. Bowel sounds are diminished or absent early in the disease. Elevation of the pulse and temperature are confirmatory in determining loss of viability of the bowel in the slowly progressive types of necrosis. The presence of a palpable mass, which sometimes is not detectable until the abdomen is relaxed by anesthesia, is pathognomonic of strangulation. The roentgenogram is valuable in determining the site of the obstruction and in detecting signs of gangrene but must be correlated with the clinical picture. The following signs are helpful signs in diagnosis of strangulating obstructions: (1) the presence of a gas filled, closed loop; (2) demonstration of a fluid-filled loop, producing a soft tissue shadow (pseudotumor); (3) failure of gas-filled loops to rise in the erect patient; (4) loss of mucosal pattern in a distended loop.

Electromyography in Neurological Diagnosis.—The nerve and the muscle form a physiological unit that generates power resulting in voluntary motion. Electromyography analyzes the electrical activity of human muscles. This report explains the principles of electromyography in their application to lower motor neuron disease, and it is based on observations in 2,500 cases. A unipolar insulated needle with only the very tip exposed is used as the active electrode and is inserted into the muscle tissue. The reference electrode is placed adjacent to the active electrode either on the skin or subcutaneously if a needle is used; in addition, a ground electrode is placed on one of the patient's limbs. The reference and the active electrodes are led to the electromyograph high-gain, push amplifier, then to the loudspeaker, cathode-ray oscilloscope, and tape recorder. Thus, normal motor units, polyphasic motor units, fibrillation of denervation, and fasciculation action potentials can be heard, seen, photographed, and recorded. Marinacci discusses and reproduces recordings showing motor unit action potentials in normally innervated muscle and in denervated and regenerating muscles. Descriptions are given of the electromyographic observations on patients with different types of nerve lesions. Electromyography is of greatest value in peripheral nerve injury; this method is to nerve injury what x-ray visualization is to bone fractures. It will reveal complete interruption of the nerve, partial involvement, reversible physiological block, psychological block, and the status and degree of nerve regeneration. Motor units, either normal or abnormal, are generated only during voluntary efforts. Fibrillation of denervation voltages and fasciculation appear when the muscles are at rest. Electrical silence is present when a normal muscle is completely relaxed as well as when the muscle tissue has been replaced by fibrosis. Degenerative motor units and fibrillation of denervation denote lower motor neuron disease. These are seen in diseases which involve the anterior horn cells, roots, plexuses or peripheral nerves, whether the cause is infectious, traumatic, degenerative, neoplastic, vascular, toxic, or compression. Electromyography is a laboratory procedure, and its findings must be correlated with the clinical picture.

Diabetes During Treatment with Cortisone and Corticotropin.—Bookman and associates found that diabetes developed in five patients who were treated with corticotropin and/or cortisone. The character and course of the diabetes was compatible with the features of steroid diabetes. All patients studied were predisposed to diabetes mellitus. In four, diabetes was known to be present in immediate family members, and in one there was a questionable history of glycosuria 10 years previously. None of the patients had fasting hyperglycemia or glycosuria while hospitalized prior to the institution of hormonal therapy. Diabetes disappeared in four patients after therapy was terminated, or after the dosage had been reduced to minimal maintenance levels. The fifth patient, who had transient glycosuria 10 years prior to treatment, had an abnormal glucose tolerance reaction one year after the cessation of hormonal therapy. Corticotropin seemed to have a more potent diabetogenic effect. Four of the patients received both hormones, but diabetes was observed only during the administration of corticotropin. The fifth patient, in whom diabetes developed during cortisone therapy, was suspected of having subclinical diabetes mellitus. It is suggested that impairment of carbohydrate tolerance developing in diabetics under stress situations may represent instances of steroid diabetes precipitated by overactivity of the pituitary-adrenal mechanisms and superimposed on pancreatic insular insufficiency.

Biopsy Techniques in Intrathoracic Lesions.—There is consensus of opinion that ideal treatment of intrathoracic lesions requires an accurate histological diagnosis. While bronchoscopic and esophagoscopic biopsies have been widely accepted as means of establishing a definite diagnosis of pulmonary and mediastinal lesions, there are three other biopsy techniques available for this purpose that do not appear to have been generally utilized. These include (1) resection of the deep cervical pad and the lymph nodes that lie within it, (2) biopsy of a mediastinal mass by thoracotomy, and (3) direct lung biopsy by thoracotomy. Cases illustrating the use of each of these three methods are described. The first procedure was of assistance in the diagnosis of three cases of Hodgkin's disease, one case of Boeck's sarcoid, and one case of anaplastic carcinoma, which was probably bronchogenic and was metastatic to lymph nodes. The second method was useful in cases of mediastinal tuberculoma, Boeck's sarcoid, and sclerosing hemangioma. The third method was of value in the study of diffuse bilateral pulmonary lesions such as those of sarcoidosis, Löffler's syndrome, and alveolar cell carcinoma of the lung. These three methods were used by the authors in an appreciable series of cases and in almost every instance it was possible to establish a definite histological diagnosis. The procedures occasioned minimal morbidity and no mortality. They appear to merit more widespread use in the investigation of intrathoracic lesions posing difficult diagnostic problems.

Segmental Postural Drainage in Pulmonary Disease.—Segmental postural drainage consists of the selective application of the forces of gravity to the removal of fluid or semifluid material from the pulmonary parenchyma and from the bronchi in a specific bronchopulmonary segment or in several segments involved in such diseases as suppurative bronchopneumonia, lung abscess, and bronchiectasis. Twenty-one positions selected for segmental postural drainage and based on the direction of the draining tertiary bronchi of the various bronchopulmonary segments of the upper, middle, and lower lobes rather than on the surface anatomy or x-ray projection of these segments are recommended. These positions are applicable to most bedridden and debilitated patients, since they impose no strain or fatigue and require no special bed or apparatus. The coordination of postural drainage with useful adjuvants such as bronchoscopy, cough sedatives, antispasmodics, expectorants, and antibiotics is discussed. Some of the medical, surgical, and pediatric indications for segmental postural drainage are reviewed. Besides the therapeutic use of postural drainage, it may be employed also for prophylactic purpose, i. e., to prevent secretions or infectious material in the bronchi and lung from remaining in one area long enough to favor atelectasis, "drowned lung," bronchogenic spread of infection, or the complicating local and systemic effects of decreased oxygen diffusion.

Dysphagia Produced by Contractile Ring in Lower Esophagus.—Ingelfinger and Kramer report on six men who complained of dysphagia. Previously their condition had been diagnosed as cardiospasm, inflammatory stricture, diaphragmatic hernia, or psychoneurosis, but these diagnoses could not be substantiated. In each instance, the dysphagia appeared to be caused by an excessively active constriction ring that produced intermittent occlusion of the esophagus. The dysphagia was described as a painful "sticking" sensation localized under the lower portion of the sternum. The patients believed that the offending food became stuck. The intensity of the distress varied, but was at times accompanied by considerable anxiety. The distress lasted from minutes to hours; then the patients felt as if the bolus was "working through" the obstructed area, leaving an aching pain that slowly subsided. During moderate attacks, the patients tended to drink water in an effort to force the retained food out of the esophagus into the stomach. During severer episodes, they were afraid of swallowing anything. The frequency of the attacks varied. In most instances the attacks were precipitated only if the patients ate certain types of food or if solids were swallowed hastily without proper mastication. The roentgenologic appearance of the constriction was qualitatively identical, but it varied in degree. The constriction appeared as a sharply demarcated negative shadow, a ring-like band 2 to 6 mm. in width, which intersected the lumen at a right angle to the long axis of the esophagus. It was located from 2.5 to 6 cm. above the junction of the esophagus and stomach. One of the patients was relieved of dysphagia following surgical removal of the distal 4 cm. of the esophagus. Another received benefit from dilatation of the lower esophagus. The other four are able to get along satisfactorily by chewing carefully and following dietary measures. The annular constriction was not caused by a fibrous band, inflammatory stricture, cardiospasm (or achalasia), or diaphragmatic hernia. The authors feel that if the claim of several anatomists is correct that there is a physiological sphincter existing in the esophagus 1 to 2 cm. above the diaphragmatic hiatus, the constriction ring may be identified tentatively as an overactive inferior esophageal sphincter.

Effects of Drugs on Serum Amylase.—The fact that analgesics alone or in combination with a pancreatic stimulant produce an inconsistent rise of serum amylase in normal patients as well as in those with disease of the pancreas is highly significant. If, besides masking physical signs in acute abdominal conditions, analgesics may also cause aberrations of serum amylase determinations, the diagnosis of acute pancreatitis will be made more difficult. To learn to what extent serum amylase values could be elevated by analgesics, 56 tests were performed on 12 patients without any history of gastrointestinal disturbance, alcoholism, or abdominal operations. An initial serum specimen for amylase determination was drawn at least eight hours after the last meal. Following this the subject received either 0.015 gm. of morphine sulfate, 0.010 gm. of meperidine (Demerol), or 0.09 gm. of codeine phosphate subcutaneously. One-half hour later 100 units of secretin diluted in isotonic sodium chloride solution was injected intravenously to stimulate pancreatic secretion. In another test 100 clinical units of secretin alone is administered as a control. In the final control test, morphine is given without being followed by any pancreatic stimulant. Serum amylase samples were drawn at 2, 4, and 6 hours after the initial stimulus. Patients took nothing by mouth during the entire period of the test. The authors found that apaprently two conditions must be present to produce an elevated serum amylase following the injection of an opiate: obstruction to the pancreatic ducts plus the presence of a secreting gland. This is borne out by the fact that none of the patients with an elevated serum amylase level following the morphine secretion test had elevations following the injection of morphine or secretin alone. Thus neither morphine, meperidine, nor codeine causes elevated serum amylase values unless the pancreas is secreting when the analgesic is given. Such conditions exist in a patient up to four hours after a meal or with acute primary or secondary inflammation of the pancreas. Thus the interpretation applied to a serum amylase value need not be altered because an analgesic has been used.

Removal of Normal Ovaries.—It has been pointed out that at some hospitals as many as 75% of ovaries removed were found to be structurally normal. McCorriston and Van Duyne investigated the histories of 323 patients subjected to ovarian surgery at an "open-staff" maternity and gynecological hospital at which 108 physicians had surgical privileges. A total of 485 ovaries were removed, 339 in conjunction with hysterectomy. A total of 241 of the ovaries were from women less than 41 years of age. For the purpose of this report, the authors define as "normal" any ovary 5 cm. or less in its largest dimension and possessing only structures representing common physiological events in the life of the ovary. Using this criterion, it was found that 62.2% of the ovaries extirpated were structurally normal. Considering separately the records of 127 patients in whom the ovary was the primary target of the surgeon, there were 100 instances in which but a single ovary was removed. Thirty-six per cent of these ovaries were normal. Of the ovaries removed from 19 patients subjected to bilateral oophorectomy, 18% were normal. The authors feel that a more conservative attitude toward the female gonad would be beneficial.

Management of Severe Illness in Childhood.—It is generally accepted that in the shock or failure of the circulation that follows hemorrhage or trauma ("surgical" shock), transfusion of blood may be expected to restore the circulation to normal. In medical shock, however, intravenous administration of blood or fluids cannot restore the circulation, excessive amounts of blood or fluid may be harmful. An unobstructed airway, particularly if the patient is unconscious, must be the physician's first concern; suctioning may be required throughout the period of shock. To appraise the physiological nature of the circulatory failure, a history must be taken to find out whether fluid or blood has been lost by starvation, vomiting, or diarrhea and, if possible, to detect the cause of the illness, whether it is infection or poisoning. Equal parts of blood or 5% glucose in water and isotonic sodium chloride solution may be injected intravenously, but care must be taken to avoid taxing the circulatory apparatus by an expansion of the blood volume beyond normal. The patient should be kept horizontal. Moving or manipulation for diagnostic procedures should be kept to the minimum. The power of contraction of a heart enfeebled by acute intoxicating disease cannot be strengthened by digitalis. The anoxia that follows circulatory failure cannot be relieved by oxygen therapy until circulation through the lungs is restored to normal. The high fever cannot be relieved by sponging of the cold skin; cold water enemas are more effective. The small amounts of fluid permissible should be used as a vehicle for intravenous injection of an appropriate antibiotic agent if infection seems the cause. Reoprts of the use of adrenal extracts and the synthetic cortical hormones cannot be interpreted as demonstrating a significant improvement in the course of patients suffering from medical shock. Stimulants such as caffeine have not been helpful. Perhaps the usefulness of all forms of drug therapy, other than that used to combat infection, is limited by a general disturbance of cellular metabolism.

Bronchial Asthma Treated with Cortisone.—Cortisone was given for a year or more to 10 male and 9 female patients between the ages of 8 and 66 years with bronchial asthma. The drug was administered in two doses to patients receiving 50 mg. daily, in three doses to those receiving 75 mg. daily, and in four doses to those receiving 100 mg. or more daily. Repeated measurements of the vital capacity and the maximum expiratory rate were made in most patients. Both the vital capacity and the expiratory rate increased on administration of cortisone, and this increase appeared to be maximal after 10 to 14 days of treatment in most patients. Although 17 of the 19 patients have maintained a satisfactory state of health, no evidence has been obtained to date that the underlying pulmonary disease of which asthma is the manifestation has been materially influenced by treatment. In two patients who improved initially increasing asthma has developed during treatment and they may probably be regarded as failures. The chief side-effects observed in this group of patients were gain in weight in 10 patients and hypertension in 3 patients, although the latter may be coincidental. Recurrent respiratory infections may be difficult to recognize, because patients receiving cortisone often fail to develop the common subjective sensations that accompany infections; respiratory infections are often associated with relapse or exacerbation of the asthma.

Reactions to Aureomycin and Procaine Penicillin Troches.—In a controlled study of 300 patients with minor oral disorders 150 were given aureomycin hydrochloride troches or placebo troches, five troches per day for four days; the remaining 150 were given procaine penicillin G troches (5,000 units per troche) or placebo troches, five per day for four days. The reactions of these patients were evaluated and compared with those previously observed in 143 patients to whom oxytetracycline (Terramycin) troches had been given. Of 100 patients receiving aureomycin troches, 51 (51%) evidenced untoward reactions, compared with 7 (14%) of the 50 patients who received placebo troches, a statistically significant difference. Of the 100 patients receiving procaine penicillin G troches, 38 (38%) evidenced untoward reactions, compared with 7 (14%) of the 50 patients who received placebo troches, also a statistically significant difference. The reactions to aureomycin troches were severe enough to warrant cessation of therapy in 14% of the patients, moderate in 10%, and slight in 27%. Reactions to procaine penicillin G troches were severe enough to require discontinuation of therapy in 11% of the patients, moderate in 11%, and slight in 16%. With oxytetracycline troches reactions that necessitated discontinuation of therapy occurred in 14.7% of patients, moderate reactions in 16.1% and slight reactions in 22.4%. The reactions to all three antibiotics were limited primarily to the mouth and pharynx. Severe glossitis or stomatitis occurred in six patients and pharyngitis in two patients in the aureomycin treated group (8%); severe glossitis or stomatitis was noted in six patients in the procaine penicillin G treated group (6%). In the oxytetracycline series of 143 patients, severe glossitis or stomatitis occurred in 8 patients and pharyngitis in 5 (9%). Thus the types of reactions observed with aureomycin and procaine penicillin G troches were similar to those previously observed with oxytetracycline troches, but the incidence of some of these reactions differed according to the medication used. As a result of their experience, the authors suggest that antibiotic troche medication may be utilized whenever its application is specifically indicated; it is not indicated for promiscuous use or when the administration of medication less likely to produce reactions is possible.

Complications of Carotid Artery Ligation.—Of 65 patients in whom carotid artery ligation in the neck was performed for intracranial vascular abnormalities, 21 had cerebral complications (a morbidity rate of 32%) and 6 died (a mortality rate of 9%). Complications ranged from appearance of pathological reflexes to hemiplegia and other severe disturbances. The age per se of the patients did not play a part in the production of complications. Observations on the author's patients and reports from the literature suggest that there is a definite hazard in ligation of the carotid artery in the neck in the presence of active subarachnoid bleeding and that a supraclinoid vascular lesion in the vicinity of the circle of Willis imposes an equal or greater hazard. The author therefore believes that ligation, when indicated, should be deferred for two weeks after the last bleeding episode. In 16 of the 21 patients with complications arteriography was carried out; it revealed deficient collateral circulation in 7. The necessity for adequate collateral circulation in patients who are to receive ligation has been emphasized. In 9 of the 21 patients with complications there was a significant rise in arterial pressure; it is suggested that hypertension at any time after ligation may be a warning of impending danger. Thirteen of the 21 patients with complications complained of headache; hemiparesis occurred in 17, mental confusion in 7, hemisensory changes in 6, aphasia in 6 of 17 with left-sided lesions, and blindness in 2. Only three patients remained unconscious, and two of these were in coma due to bleeding when the ligation was performed. The following tentative hypothesis of the causation of complications after carotid artery ligation in the neck is presented: Insufficient blood flow secondary to ligation and deficient collateral circulation cause relative anoxemia, which produces anoxia of the terminal vessel, with dilatation, transudation of fluid, unilateral cerebral edema, and increased intracranial pressure. Compensatory arterial hypertension ensues, but its effect is blocked by the ligation. Tissue anoxia follows until the compensation point is passed, when clinical symptoms rapidly appear. Prompt removal of the ligature may re-establish adequate blood flow and oxygenation. On the basis of this concept the following suggestions for the prevention and therapy of these complications are presented: Selection of patients should be based on adequate preoperative knowledge of the dangerous cases, with emphasis on the supraclinoid and communicating artery location and adequacy of the collateral circulation. Selection of the optimum type of ligation should be aided by complete arteriography and pressure recordings. Adequate observation and testing during the first 24 hours after the ligation is imperative. Since the clip must be removed within 15 minutes and 10 minutes are usually required for such removal, the patient must be under constant observation by a nurse and tested for strength and responsiveness every five minutes for at least 12 hours. In 11 of the author's 21 patients clip removal was done and was considered lifesaving. The speed and degree of the recovery was directly related to the promptness with which the clip was removed. Although the series is too small to permit definite conclusions until more data are available, the outline of treatment may provide a basis for more active therapy when such complications arise.

Treatment of Ruptured Lumbar Disks by Spinal Fusion.—According to Cloward, in order to relieve a patient with ruptured lumbar intervertebral disk of all symptoms, both causes of disability must be considered and treated. The two causes are low back pain, primarily caused by collapse of the intervertebral disk and the resultant loose, unstable vertebral joint, and pain in the lower extremities, resulting from compression of the root at the intervertebral foramen. Consequently all abnormal mechanical factors that may compress the nerve root must first be removed, and second, the broken, movable, painful vertebral joint must be immobilized. Fusion of the vertebral bodies by a strong intervertebral graft wedged into the interspace to replace the ruptured disk seemed to be the logical procedure. The operative method employed by the author consists of subtotal removal of the ruptured intervertebral disk, including the cartilaginous plates, through a partial bilateral laminectomy. The cortical surfaces of the vertebral bodies are removed with a chisel, and three or more large full-thickness bone grafts obtained from the iliac crest are driven forcibly into the interspace. This procedure, which is described in detail, was performed on 321 patients who were followed for from six months to eight years postoperatively. Before 1946, the bone grafts used for the fusion were taken from the ilium of the patient, while since 1947 bone from a bone bank has been used successfully in 131 patients. The patients operated on by this procedure during the first five years were fitted with a low-lumbar back brace, which was worn for three months. In the last two years, with more extensive grafting of the interspace, it has become unnecessary to require the patient to wear a back brace. Since the back brace has been discontinued, patients seem to recover the normal flexibility of their spines much sooner. If the patient's occupation requires him to do heavy manual labor, including bending and lifting, he is permitted to return to this work in approximately three months, depending on the appearance of the fusion as determined by x-ray. Other patients are often able to return to their jobs within two weeks after the operation. Complete long-term cures were obtained in over 85% of the author's patients. Failure of fusion because of unexplained absorption of the intervertebral grafts occurred in only six patients. In two of these six patients, the vertebral bodies eventually fused after prolonged convalescence, while a second fusion was performed in the remaining four. Transient numbness of the foot and ankle and weakness of anterior tibial muscle were occasionally observed. It was necessary to remove the bone grafts in only 2 of the 14 patients in whom infection occurred. In all the others the wounds healed without loss of bone and the fusion was more solid than in those that were not infected. The rapidity with which patients recover from the operation and the high percentage of complete long-term cures seem to justify the conclusion that spinal fusion is the treatment of choice for ruptured lumbar intervertebral disk.

Dimercaprol in Acute Lead Encephalopathy.—Deane and associates summarize the results of treatment of 54 children with acute lead encephalopathy. The ages ranged from 15 months to 7 years. Inquiry into the source of the lead revealed that 32 had eaten lead paint and 12 had eaten plaster. Signs and symptoms included convulsions, vomiting, and neurological abnormalities. The long bones were examined in 46 of the patients, and 41 had evidence of heavy metal deposition at the metaphyseal ends. The children revealed an average blood lead level of 0.25 mg. per 100 cc., with a range of 0.08 to 0.73 mg. per 100 cc. of blood (over 0.06 mg. is considered abnormal). A positive urine test for coproporphyrin of 2+ or more is also of diagnostic value. Thirty-eight patients were treated before 1948, when treatment consisted of the use of calcium in the form of lactate, gluconate, or chloride administered both orally and parenterally and supplemented by high vitamin D intake, increased phosphorus intake, and sodium citrate. After 1948 patients were treated with dimercaprol, in the form of a 10% solution of dimercaprol in benzyl benzoate and oil. The therapeutic regimen was to give 3 mg. of dimercaprol per kilogram every four hours for a total of 10 days. Supportive measures included in both series the use of barbiturates, intramuscular magnesium sulfate, and, in some instances, drop ether to control the convulsions. The fluid balance was maintained, and chemotherapeutic agents were used whenever infection was present. Of the 38 treated without dimercaprol, 10 died, whereas only one of the 16 treated with dimercaprol died. Because of this striking difference in the mortality of the two groups, the authors advise that treatment with dimercaprol be continued in acute lead encephalopathy.

Isolated Myocarditis in Infants.—Isolated myocarditis, which was first described by Fiedler in 1899, is a nonspecific, idiopathic disease characterized by progressive or sudden heart failure, frequently associated with various aberrations of the cardiac-conducting mechanism. The only constant structural changes are inflammation of variable type, confined to the myocardium, and cardiac hypertrophy. Boikan differentiated three types. The first is an acute diffuse lesion from which, he felt, recovery was possible. The second is a more chronic form that causes death in a period of months. The third type is manifested by recent and remote cardiac changes that ultimately result in death from progressive heart failure. While the disease usually occurs in young adults, the authors found reports of 26 young children (up to 22 months) in whom the disorder was either proved or suspected. The authors describe two infants in whom they observed the disease. The first of these infants had an acute, diffuse, myocardial lesion that seems to correspond to the first type described by Boikan. It is difficult, however, to conceive of recovery in a heart so intensely inflamed. The disease in the second infant, in whom a clinical diagnosis was established on the basis of bradycardia, low-grade fever, syncope, and changing electrocardiograms for which no other apparent cause could be discovered, corresponded to Boikan's second group. Although the fever was altered by penicillin, no therapeutic responses were elicited by sulfadiazine or atropine in high dosage, and these agents failed to prevent syncope and death. Isolated myocarditis should be considered in the differential diagnosis of cryptogenic cardiac arrhythmias and cardiac enlargement occurring in infants.

Postmeningitis Complications.—Fox observed that not infrequently patients who had recovered from meningitis would revisit the hospital 5 to 10 years after their illness with symptoms such as headaches, loss of hearing or hearing defects, muscle pain, fainting spells, muscle twitching, or, rarely, convulsions. Frequently the family physician would call the hospital regarding the patient's record. Understanding of postmeningitic symptoms has become more important since the mortality rate has been greatly decreased by the use of sulfonamides and antibiotics. A questionnaire regarding complications and sequelae was sent to 323 patients who had been treated for acute meningococcic meningitis at a Milwaukee hospital between 1936 and 1945. Nearly half of those who responded had some symptoms. Headache was the commonest residual. It was localized most frequently to the occipital area. About half (88) of those who replied complained of what the author designates as cord symptoms, that is, joint or muscle pain and muscle twitchings. Fainting was reported by seven patients and convulsions by one. Another questionnaire was sent to the 22 patients who complained of impairment of hearing. Since two of the 16 who responded stated that their hearing had been defective before the attack of meningitis, only 14 are considered. One patient reported eventual complete recovery and six others improvement in hearing; the other seven experienced no improvement. Changes in weather, altered working conditions, and drinking large amounts of water aggravated the residual symptoms in some of the patients. A fibroblastic proliferation inhibiting free circulation of cerebrospinal fluid and resulting also in a circulatory embarrassment to the brain and spinal cord may be the pathological change responsible for the postmeningitic symptoms. The pathological change causing the auditory impairment is in the temporal bone area. There is extension of the exudate by way of perineural spaces of the eighth nerve and perivascular spaces of modiolar vessels. The exudate leads to atrophy and degeneration of the neuroepithelium of the cochlea and vestibule.

Trichlorethylene in Obstetrics.—Morgan and associates used trichlorethylene as an anesthetic agent in the delivery of 140 multiparous and 14 primiparous women. No maternal deaths occurred, nor did any of the babies show signs of respiratory depression or difficulty. More can be accomplished with trichlorethylene than is usually thought possible. General anesthesia can be obtained with it, and it provides adequate anesthesia for forceps applications, episiotomies, and repairs. Episiotomy and repair were done in 95 cases. Forceps were used in 60 cases, some liberalization in the indications being entertained because of the clinical trial of trichlorethylene. Postpartum nausea and vomiting were rare. Relaxation of perineal structures was not good, however, and the authors do not recommend trichlorethylene for women in whom delivery is difficult, nor in any patient whose delivery will be facilitated by complete relaxation of the muscles of the pelvic floor, i. e., breech delivery. Retrograde amnesia followed in almost all patients, and for this reason, trichlorethylene has found ready patient acceptance. The possibility of using trichlorethylene in twin deliveries is discussed. Few side-effects were encountered. It was the impression of several observers that labor was shortened because of the psychological support offered by the hand mask. Supplementary anesthesia was required in only three cases. As a rule, trichlorethylene anesthesia should be started only in cases for which it obviously will suffice, but if necessary, a change can be made to use of open drop ether.

*Congenital Afibrinogenemia: Report of Case. H. A. Lawson.—p. 552.

Congenital Afibrinogenemia.—Congenital afibrinogenemia is a rare disease that was first described by Rabe and Salomon in 1920. After briefly citing several other reports, Lawson presents the case of a 19-year-old woman, who was first seen at the age of 16. She had had several episodes of uncontrollable bleeding from lacerations resulting from childhood accidents. The hemorrhage could not be arrested until she was given blood transfusions, which on each occasion caused prompt cessation of bleeding. On two or more occasions troublesome bleeding had followed extraction of teeth. She had intervals of months or years without difficulty of any sort, the hemorrhage occurring only as a result of injuries. She had never had epistaxis, bleeding gums, hemarthrosis, or hematuria, but she almost always had several black-and-blue spots on her arms or legs as the result of slight trauma such as bumping against furniture. There was no consanguinity of the parents (a situation that has been reported in other cases of this disease). A brother had died three days after birth as a result of uncontrollable hemorrhage from the umbilical cord. The patient's mother had a history of easy bruising throughout her life but had never had any serious hemorrhage. Examination of the mother's blood revealed a mild deficiency in fibrinogen. Laboratory examinations on the patient were negative except for the complete incoagulability of the blood due to absence of fibrinogen. This case was of unusal interest because menstruation was entirely normal; it clearly demonstrated that a normal menstrual flow is possible despite the inability to form a fibrin clot. As regards the advisability of marriage and child-bearing, it is necessary to consider the safety and welfare of the patient and the possibility of inheritance of this serious disease by any children she might have. In this case there is a strong familial tendency, as shown by the partial deficiency of fibrinogen in the mother and the probability of complete afibrinogenemia in a brother.

*Overwhelming Bacteremic Shock Produced by Gram-Negative Bacilli: Report of Four Cases with One Recovery. A. I. Braude, J. Siemienski, D. Williams and J. P. Sanford.—p. 23.
Clinical Experience with New Indandione Derivative: Preliminary Report. I. F. Duff, E. W. Dennis, P. E. Hodgson and W. W. Coon.—p. 43.

Bacteremic Shock Produced by Gram-Negative Bacilli.—Braude and associates observed four cases of overwhelming bacteremic shock. Two resulted from naturally occurring infections, another from transfusion of contaminated blood, and in one the origin of the bacteremia was not definitely determined. These cases illustrate the clinical nature of a syndrome that is not usually defined as a separate entity. Three sets of symptoms were observed: (1) chills, fever, and sweats; (2) severe abdominal pain associated with voluminous stools, which were sometimes liquid or bloody, and severe muscular pain accompanied by such tenderness to touch that the patients often objected to being handled; and (3) severe hypotension (average blood pressure about 65/35) accompanied by rapid labored respirations, mental confusion, apprehension, restlessness, cyanosis, and anuria. Symptoms observed in addition to these three groups included a bleeding tendency and jaundice. A paracolon organism was isolated from the blood of each of two patients. The blood of one of these also contained innumerable Aerobacter aerogenes. Two other patients also had two species of bacteria. In one Proteus and Enterococcus organisms were repeatedly isolated from the blood. In another patient both Escherichia freundii and a coliform organism of intermediate type were present in large numbers in the contaminated blood transfused into the patient, but only the paracolon was recovered from the patient's blood. The authors describe studies with antibiotics. One of the four patients in shock was successfully treated with antibiotics, arterenol, and cortisone. There should be no hesitation in using all the antibiotics that may be active against gram-negative bacilli. The patient in whom therapy was successful was treated with aerosporin (polymyxin B), aureomycin, chloramphenicol, and penicillin. Studies bore out the logic of using several antibiotics; aerosporin proved to be highly bactericidal against the Esch. freundii and the other coliform isolated from the patient. There was no doubt about the effectiveness of arterenol, but the value of cortisone was not clear. In all four patients massive numbers of bacilli were detected in the blood; in one they were so numerous that they could be demonstrated microscopically in a smear made from a drop of capillary blood. For comparison the authors also recorded observations on two patients with bacteremia due to gram-negative bacilli who did not experience hypotension. The blood of the two patients who did not experience shock was not heavily infected.

•Valvulotomy for Pulmonary Stenosis Performed Through the Main Stem of Pulmonary Artery Utilizing a Special Ring Clamp. T. Søndergaard.—p. 362.

Improved Technique of Valvulotomy for Pulmonary Stenosis.—Pulmonary valvulotomy is indicated in patients with symptoms due to pure pulmonary stenosis with or without an atrial septal defect, and there is much in favor of this procedure in cases of tetralogy of Fallot with valvular pulmonary stenosis. While satisfactory results may be obtained with a transventricular approach, the arterial route offers the following advantages: Damage to vital tissue is avoided. The surgeon is working behind the stenosis through a vessel that is usually dilated and spacious, with low pressure, and without disturbing the circulation or placing an additional load on the heart, which already has been under great strain. A ring clamp is described that permits a safe access to the interior of the pulmonary artery without any significant loss of blood and facilitates performance of valvulotomy through the main trunk of the artery. The procedure on the valve thus can be done deliberately and slowly, and the difficulty in locating the stenosed orifice is eliminated. Four illustrative cases in which this technique was used for valvular stenosis of the pulmonary artery in children between the ages of 6 and 13 years are reported. Thoracotomy was performed, with resection of the left fifth rib, and the ring clamp was placed on the pulmonary artery for 20 minutes. The blood pressure dropped 10 to 20 mm. Hg during the actual manipulations on the valve but returned to normal within seconds as soon as the instruments were withdrawn. The perfect control over the blood loss offered by the ring clamp made it possible to pass the cutting and dilating instruments through the orifice, which had been easily located with a probe, without damaging the normal valve. A valvulotome with retractable blades and Brock's expansible dilator were used. The closure of the incision in the artery with a continuous everting suture proved less difficult than the suture of the ventricular wall. As a result of his experience, the author states that in selected cases the arterial route has a decided advantage over the transventricular approach in patients with pulmonary valvular stenosis.

Adrenocortical Response to Corticotropin, Cortisone, and Ascorbic Acid in Children.—Investigations on the urinary excretion of steroids in normal children indicate a very low excretion of 17-ketosteroids until the beginning of puberty. The rapid yearly increase in excretion from that time must be due to a maturation of this function of the adrenal cortex. The ability of the adrenal cortex to produce corticoids seems to be fully developed from birth. The adrenocortical response to corticotropin as measured by the changes in the urinary excretion of corticoids and 17-ketosteroids was studied in 15 children. The results are compared with those obtained in adults. The changes in corticoids were the same in the two groups but a clear difference was found with regard to the 17-ketosteroids, the increase after administration of corticotropin being much smaller in children than in adults. The determination of the urinary corticoids probably offers a more sensitive and a more direct measurement of the adrenocortical response to corticotropin in children than the determination of 17-ketosteroids. Results obtained with cortisone administration in three children suggest that the 17-ketosteroids in children are derived from a conversion of corticoids. The steroid excretion was altered in an unexplained manner when ascorbic acid was given in addition to corticotropin. In 8 of 10 cases the corticoids decreased during the first three days of ascorbic acid administration, followed again by a gradual increase during the next few days. The 17-ketosteroids changed to a lesser degree but on the whole in a parallel manner. A reversed excretion pattern was found in two cases. Control experiments were performed with three children to whom ascorbic acid was administered alone. The steroid excretion was unaltered in all cases. Cholesterol had no influence on the steroids. In two cases infections occurred during the experiments, and in both cases a typical stress reaction was observed in spite of the simultaneous administration of corticotropin.

Corpus Luteum Hormone in Treatment of Biliary Dyskinesia.—Biliary dyskinesia in patients who have not been operated on may be defined as a disturbance in the reciprocal relations between the motility of the gallbladder and that of the sphincter of Oddi. Delayed emptying of the gallbladder is a common radiological finding and may be found in patients without symptoms, in patients with symptoms of dyspepsia, and in patients with biliary colic. Biliary dyskinesia, as shown by delayed emptying, is frequently only one manifestation of general dyskinesia in the gastrointestinal and genitourinary tracts, and may be associated with other conditions such as peptic ulcer, spastic colitis, pancreatitis, carcinoma, and renal calculus. Hormonal influences are known to be responsible for biliary dyskinesia occurring in women in connection with menstruation and during pregnancy. Intensification of dyskinetic symptoms in the digestive tract before menstruation may be due to a disturbance in the estrogen-progesterone balance, or to a relaxing effect exercised by the corpus luteum hormone on smooth muscle in the organs connected with the genital apparatus by reflex nervous pathways. Corpus luteum therapy was tried in 27 women, aged 30 to 76, 11 presenting the postcholecystectomy syndrome with typical biliary colic and the other 16 having gallbladder dyskinesia of the delayed emptying type. Premenopausal patients received one injection of 10 mg. of progesterone (Progestin) once a month from 8 to 15 days before the beginning of the menstrual period; in some cases the dose was increased to two injections monthly. Menopausal and postmenopausal patients received one injection weekly for three weeks. A period of waiting then followed, after which in some cases injections were resumed at longer intervals. Striking improvement or complete relief of symptoms was obtained in all but six cases. Seven of the 11 patients with the postcholecystectomy syndrome in particular became symptom free. The fact that postmenopausal women were benefited by the corpus luteum hormone shows that it has a sedative action that may be spasmolytic in character.

Schizophrenia and Schizophrenia-Like Psychoses After Brain Trauma.—In definitely exogenous psychoses a causal connection with brain trauma can usually be established even if there is a long period between the trauma and psychosis. If, however, the psychoses are endogenous, a causal connection with trauma is only rarely demonstrable, unless the brain trauma was especially severe and there is a chronologic relationship (symptoms bridging the interval). Even in cases of severe trauma, the probability of a connection with an endogenous psychosis may be all that can be assumed, because since schizophrenia is relatively frequent, an accidental concurrence of trauma and schizophrenia is always possible. In a review of the literature the authors could find only 26 cases in which a causal connection between a schizophrenia-like psychosis and trauma seemed probable and 16 in which it seemed possible. They add reports of five new cases with schizophrenia symptomatology after severe brain injuries, which were in the frontal brain in four cases and in the temporal lobe in one case. Another group of patients with brain trauma had psychoses that resembled schizophrenia but could be differentiated from it. The authors designate these as symptomatic psychoses. These included two patients with hallucinations, the brain lesions being located in one case certainly and in the other case probably in the right parietal region. There was also one case in which hallucinations concurred with Korsakoff's psychosis that resulted from trauma. Finally the authors present observations on three patients with paranoid psychoses in whom there had been brain trauma followed by convulsive attacks. In these cases it is likewise difficult to ascertain whether the concurrence of trauma and psychosis is accidental or whether the psychosis is a sequel or symptom of the convulsive disorder. In one of the three cases, the last possibility seemed proved, since the psychosis appeared immediately after a series of convulsive attacks and disappeared following surgical removal of a missile and of a cyst from the right temporal region. The authors feel that psychoses in persons in whom trauma to the brain has resulted in convulsive attacks are usually symptomatic, that is, the result of the convulsive attacks; however, definite proof cannot be furnished. In only one of the cases presented did schizophrenia exist also in blood relatives, and in another case it seemed possible that the psychosis was a recurrence of an earlier psychotic attack.

Diagnosis of Intestinal Tuberculosis.—Roentgenographic examination disclosed abnormalities of the stomach in 187 of 700 patients with open pulmonary tuberculosis after a barium meal and after barium enema. Tuberculous changes were suspected in 89 of the 187 patients, but this suspicion was verified in only 27 patients (4%). Of 51 patients who died of open pulmonary tuberculosis and in whom necropsy was performed, 23 (45%) had specific changes in the intestines. Of these 23 patients, 14 while alive had been subjected to roentgenologic examination of the gastrointestinal tract, and in only 8 of these 14 patients had a diagnosis of intestinal tuberculosis been based on the results of this examination. In the remaining six patients in whom pathological changes had not been demonstrated by roentgenologic examination, the latter had been carried out one to four years before death, and intestinal tuberculosis may have developed in the interval between the roentgenologic examination and death. Of the 28 patients in whom necropsy revealed no evidence of intestinal tuberculosis, 16 had been subjected to roentgenologic examination while alive; results of this examination had been negative in all. A total of 242 bacteriological examinations of feces were carried out in 34 patients. Only 2 of 33 cultures obtained from the feces of tuberculous patients with intestinal involvement were positive for Mycobacterium tuberculosis. Studies of the feces according to Ziehl-Neelsen's method did not yield better results. As a result of his experience, the author states that only roentgenologic examination with a subtle technique may offer considerable aid in the diagnosis of intestinal tuberculosis, although the limitations of roentgen diagnosis are revealed by comparison of the roentgenologic and necropsy findings. Early cases of intestinal tuberculosis are rarely detected by roentgenologic examination. Bacteriological examinations of feces with direct preparation or culture should be omitted because they are without value.

Intratesticular Estrogenic Implants in Prostatic Cancer.—When estrogenic implants are used in the treatment of prostatic cancer, pellets of estrogenic substance are usually placed under the skin. Darget and his associates reasoned that their effectiveness might be increased if they were implanted directly into the tissue on which they are to act, namely, the testis. Experiments on rats confirmed the soundness of this hypothesis and seemed to justify a trial in human subjects. The first patient was a man with a highly malignant prostatopelvic carcinoma who was deriving no benefit from the oral administration of estrogens. The implantation of 100 mg. of diethylstilbestrol into each testis had the following results: the 17-ketosteroids completely disappeared from the urine, the pelvic tumor decreased in size, and there was a general improvement in the state of health. When three months later a unilateral castration was done for control purposes, 67 mg. of the pellets had not been absorbed as yet. The examination of the removed testis showed, in comparison with the biopsy made before the implantation, a nearly complete atrophy of the seminal line and of the interstitial tissue. After having tried this method on 10 patients, the authors believe that the method is not dangerous and is much more effective than the usual subcutaneous implantation.

Aortic Occlusion in Infancy. C. Marks and B. M. Fehler.—p. 709

Toxoplasmosis and Mental Deficiency.—Of 698 mentally deficient patients, most of them children, 55 showed positive toxoplasmin skin and dye reactions. The incidence of positive reactions increased with advancing age. The 55 positively reacting patients were examined physically, ophthalmoscopically, and radiologically for signs of toxoplasmosis. The criteria cited by Sabin in 1948 served as a guide. They include internal hydrocephalus or microcephaly, chorioretinitis with predilection for the macular region, convulsions and other signs of involvement of the nervous system, and cerebral calcification. In two cases eye lesions suggestive of toxoplasmosis were found. Radiologic examination and lumbar puncture showed nothing suggestive of toxoplasmosis. In none of the cases could the mental defect be definitely attributed to toxoplasmosis. In some cases other causal factors were present, for example, epiloia (tuberous sclerosis), phenylketonuria, or mongolism. It was concluded that in mental institutions or elsewhere a positive toxoplasmin reaction is acquired like a positive Schick reaction with increasing age and is very infrequently associated with clinical toxoplasmosis, and that toxoplasmosis is not a common cause of mental defect.

Endometrial Tuberculosis.—Apparently healthy young women complaining of menstrual disturbances or sterility are sometimes found to have endometrial tuberculosis. Endometrial biopsy indicates the diagnosis but does not establish it, because various other conditions may give rise to pseudotuberculous manifestations. Attempts to demonstrate Koch's bacillus by guinea pig inoculation and direct cultivation have hitherto proved unreliable, but Sevin of the Pasteur Institute at Lille developed a method of using endometrial fragments in Petragnani and Dubos mediums that provides accurate and dependable diagnostic information. Positive cultures confirmed a diagnosis of endometrial tuberculosis that was indicated by biopsy in eight patients, and in three others in whom the biopsy findings were negative tuberculosis was discovered when routine cultures proved positive. The value of endometrial biopsy as a diagnostic procedure is shown by the fact that Koch's bacilli were demonstrated in all cases in which the biopsy findings were positive; when the findings are doubtful or negative, the information obtainable from the cultures is invaluable. Endometrial cultures may also be used to determine the efficacy of treatment. The best proof of cure in patients in whom sterility is the result of endometrial tuberculosis is the establishment of a normal intrauterine pregnancy; failing this, however, reduction in bacillary virulence or conversion of cultures from positive to negative is an excellent indication of the progress being made. Streptomycin and *p*-aminosalicylic acid, given systemically and by intrauterine instillation, is the treatment preferred by the authors, but care must be used in applying *p*-aminosalicylic acid locally because it causes pain. The latency, benignity, and surprising lack of dissemination characteristic of endometrial tuberculosis have been attributed to low bacillary virulence, but the bacilli recovered from the cultures in the authors' cases have all been normally virulent. A recent suggestion by Aschheim that the stroma of the endometrium may form part of the reticuloendothelial system, which is known to be highly resistant to infection, offers a possible explanation for these phenomena.

Alkaptonuric Osteoarthropathia and Osteoporosis.—Bürger and Schulze call attention to the localization of ochronotic pigment deposits in the so-called bradytrophic tissues on the basis of observations on three patients with alkaptonuria. They show that the degenerative pigment deposits that are characteristic of ochronosis are found particularly in tissues that have relatively few capillaries, and to which they apply the term bradytrophic. Ochronosis is to a certain extent a method of vital staining of the bradytrophic tissues and corroborates the impression gained by chemical analysis. This has shown that these tissues are traps for waste products, that is, as they become dehydrated or consolidated as the result of aging, they take up by diffusion deposits of metabolic wastes. Apparently a considerable period is required for the formation of ochronosis, and not every patient with alkaptonuria lives long enough for ochronosis to become manifest. The three patients with alkaptonuria gave the authors the opportunity to study changes in the chondro-osseous system. They found that the degenerative changes were not limited to the syndesmoses or to the articular cartilage, nor were the bone changes dependent only on primary changes in the cartilages. Even bones that were far removed from joints showed morbid structural changes, which roentgenologically gave the impression of a strand-like osteoporosis. The authors conclude that the sequel of prolonged alkaptonuria is osteochondroarthrosis deformans. The severe osteoporosis found in these patients can be traced to the chronic acidosis due to homogentisic acid.

Isoniazid in Tuberculous Meningitis.—From his experiences with the use of isoniazid in the treatment of 15 children with tuberculous meningitis the author concludes that this drug is of greater value than streptomycin in the treatment of the disease. To prevent the development of resistance of the tubercle bacilli to the drug, it is advisable to give it with streptomycin or *p*-aminosalicylic acid. When the drug is given extrathecally, the daily dose for children is 7 to 10 mg. per kilogram of body weight. Daily doses of 15 or 20 mg. can be given extrathecally only in late, acute cases and for a short time. Intrathecal administration is usually unnecessary, as the drug easily permeates the blood-brain barrier. It seems to be indicated only in cases observed late in the course of the disease, in some patients in coma, and probably in some infants. The daily intrathecal dose is 0.50 to 0.75 mg. per kilogram of body weight in adults and 0.5 to 1 mg. per kilogram of body weight in children. To prevent recurrences from reactivation of either meningeal or extrameningeal tuberculous foci, it is advisable to give the treatment without any interruption for as long as necessary (no less than five months in the cases observed by the author). Isoniazid seems to prevent blockage of the cerebrospinal fluid but is of no avail for controlling established blockage, which calls for neurosurgery.

Prostatectomy According to Hryntschak's Technique.—Foret and Maquinay performed 100 prostatectomies with the patients under high peridural anesthesia, preferably between the 8th and 10th dorsal vertebra, using Hryntschak's technique. This technique involves a suprapubic, transvesical approach with attachment of the site of the incision in the bladder to the aponeurosis of the rectus muscle to prevent soiling of the perivesical tissues. The adenoma is then enucleated with the finger while the prostate is steadied by the assistant's fingers in the patient's rectum. Two supporting sutures of chromic absorbable surgical suture no. 1 are placed at the circumference of the neck at positions corresponding to 2 o'clock and 10 o'clock on the face of the clock. The posterior lip of the neck is resected with scissors. A whip-stitch suture is then started at the position corresponding to 2 o'clock following the entire circumference of the neck, being crossed at each point and terminated at the mooring point corresponding to 10 o'clock. The whip-stitch provides a more complete suture, securing absolute hemostasis not only of the pedicles of the prostate but also of the small vessels that are bleeding on the surface of the cross section. The bladder is closed with purse-string sutures using chromic absorbable surgical suture no. 4. Systematic vasectomy is carried out and a catheter fastened at the prepuce; the urinal connected with the catheter is emptied every half hour for at least 48 hours to make sure the catheter is permeable. Except for eight patients with severe heart disease, all the other patients were allowed to get out of bed on the day after the operation. Only one of the 100 patients had postoperative phlebitis and only one died of pulmonary embolism. Sixty-six patients of an average age of 67 years obtained a complete cure with definite closure, surgical healing of the wound, and normal micturition within 10 days after the surgical intervention, and had not the slightest annoyance later on. In these patients the catheter was left in place for four days on the average. In 10 patients recovery within 10 days was incomplete because of minor complications, i. e., parietal suppuration in 3, incontinence in 2, broken catheter in 1, phlebitis in 1, secondary vesical lithiasis in 1, and abnormal dilatation of the prostatic urethra in 2. Five patients apparently recovered within 10 days, but a second operation became necessary later on; postoperative hemorrhages occurred in three of these patients (two weeks after the operation in one). Urinary fistulization occurred in 15 patients; of 25 patients with urinary infection before the operation, fistulization occurred in 8, while only 7 of the 75 patients without infection had a postoperative urinary fistula. There were four deaths within half an hour to 17 days after the intervention, resulting from sudden cardiac failure, myocardial infarction, pulmonary embolism, and bronchopneumonia respectively. A large number of the patients obtained a rapid and complete cure without any suffering. Using Hryntschak's technique the space of Retzius is not opened, and not a single case of pubic osteitis has been reported.

Kernicterus and Prematurity.—Kernicterus has been attributed to sepsis, to hepatitis, to an undetermined toxin, and, more recently, to Rh immunization. The view commonly held today is that expressed by Claireaux in 1950 when he said that "nuclear jaundice is always associated with icterus gravis neonatorum resulting from hemolytic disease." Recently, however, doubt has been cast on the validity of such statements by investigators who observed kernicterus in babies without pathological or serologic evidence of hemolytic disease. In this paper Govan and Scott report observations on 10 infants with kernicterus in whom there was no Rh incompatibility between mother and fetus. All were premature, the average birth weight being 3 lb. (1,360 gm.) and the average duration of pregnancy 32 weeks. In each case there was some complication either during pregnancy or at the time of birth. In four cases there had been antepartum hemorrhage due to placenta previa. Severe preeclampsia affected the mothers of two other infants. The cord prolapsed in one case during labor and had to be replaced. Another infant was the second of twins presenting by the breech, and version had to be undertaken before delivery could be effected. A spontaneous but rather precipitate breech delivery occurred in another case. In the 10th case the labor was prolonged for 86 hours. The infants were feeble at birth, cyanosed, and difficult to resuscitate. All were treated by the usual methods for premature babies. Heat and oxygen were supplied, and each received vitamin K and penicillin. Jaundice appeared on the 4th day in these children, and the time of death varied from the 4th to the 9th day of neonatal life. These 10 cases were selected from a larger series because they exhibited the typical changes and there was no question of blood incompatibility. All had negative reactions to the Coombs' test and the blood-groups of mother and child, as regards both ABO and Rh factors, were similar. The brain lesions found had the same anatomical distribution and histological appearance as those found in kernicterus due to erythroblastosis. Similar lesions have been found in premature infants dying during the first three days of neonatal life before jaundice appeared, indicating that pigmentation is a secondary feature. From a comparison with lesions found in known states of asphyxia, the authors are led to the conclusion that damage to the brain occurs at the time of birth and is due to anoxia. The lesions of erythroblastosis are probably of similar origin.

Intra-Aortic Blood Transfusion.—There is evidence that for blood transfusions in severe oligemic shock the intra-arterial route has advantages over the intravenous route, but infusions into peripheral arteries involve the danger of spasm and thrombosis. Intra-aortic infusion, which Haxton has been using for 18 months, is free from such difficulties. He conceived it in the course of hundreds of lumbar paravertebral sympathetic blocks, in which he observed that the aorta could be easily punctured from the left side and that no sequelae resulted. Transfusion into the abdominal aorta at the level of the third lumbar vertebra with a special stepped needle has proved simple and free from complications in 20 cases. In 3 of the 20 patients, whose ages ranged from 2 days to 84 years, the intra-aortic transfusion was repeated. Owing to the serious nature of the illness, there have been some fatalities; but in only one case did the transfusion appear to have a deleterious effect. In cases with repeated gastrointestinal hemorrhage this method rapidly restored the general condition and allowed the safe performance of early operation. In other cases with acute oligemia rapid improvement followed transfusions of moderate size. Transfusion can be made under direct vision into the aorta during thoracic and abdominal operations should the need arise. The necessary apparatus should be ready and sterile for immediate use.

Cation Exchange Resins.—Ammonium-potassium cation exchange resins were used in the treatment of a group of 16 patients, which included seven patients with essential hypertension, seven with congestive heart failure with edema, and two patients with cirrhosis of the liver with ascites and edema. Patients with symptoms of renal insufficiency were not included in this group. The drug was given in daily doses of 50 gm., which was given in three fractional doses at regular intervals, for from 1 to 20 weeks. The daily amount of sodium allowed in the diet of the patients was between 800 and 1,000 mg. The tolerance of all patients to the drug was excellent. In none of the patients were symptoms of acidosis, hypokalemia, and salt depletion observed. In the seven patients with essential hypertension, the symptoms greatly improved. The decrease in the blood pressure was slight and transient. In the only patient in whom hypertension markedly diminished, the blood pressure returned to its pretreatment level on the fifth day after discontinuation of treatment. In the seven patients with congestive heart failure, from a selected group of patients in whom the administration of cardiotonics, diuretics, and a low sodium diet had previously failed, the treatment with cation exchange resins resulted in increasing diuresis and in diminishing edema. In the two cases of cirrhosis of the liver, ascites, and edema diminished. The authors compare the effects of the treatment with those they obtained in a group of 700 patients with essential hypertension from the administration of the rice diet, as previously reported. They conclude that cation exchange resins have effects similar to but not as good as those obtainable with the rice diet in essential hypertension. Continuous or periodic cation exchange resins treatment is of value as an adjunct to a low sodium diet when the latter has to be given for a long time. The treatment is of value in cases of congestive heart failure with edema and of cirrhosis of the liver with ascites and edema that do not respond to standard treatment. In these cases the resins potentiate the effects of mercurial diuretics and at the same time make the diet more palatable than the strict low sodium diet.

*Streptomycin Therapy in Adults with Tuberculous Meningitis. P. Nicolaj. —p. 447.

Streptomycin in Adults with Tuberculous Meningitis.—Nicolaj reviews the results in all patients older than 13 years who were admitted to the University of Bologna pediatric clinic (streptomycin section) with tuberculous meningitis from 1947 to 1951 and had streptomycin therapy. A total of 45 children were admitted but only 33 were treated only by the author, 12 having had previous treatment elsewhere. Twenty-seven patients recovered; one has been well for more than four years, nine for more than three, two for more than one year, and the others for less than one year. There was a relapse in three patients, but two of them recovered with streptomycin therapy, and the third, who was still being treated at time of writing, had improved and had a normal fluid picture. The author used streptomycin diluted in water (1 gm. in 20 cc.), and at time of administration he diluted it again in 1 to 2 cc. of lukewarm isotonic sodium chloride solution. He used both the intrathecal and the intramuscular routes, since the intramuscular route alone had given negative results. Intrathecally the dose was 50 to 80 mg. daily for three months; often to the patients whose condition was severest two intrathecal injections were given every day in doses of 40 to 50 or 60 mg. each time for 15 to 30 days. After three months, if the temperature had returned to normal and the fluid picture was improved, the drug was given every two days and this was continued for two months. Then the time interval between injections was gradually increased until therapy was discontinued in about 8 to 10 months. When onset of a spinal block was suspected, the drug was given by the suboccipital route in doses of 15 to 20 mg.; from 90 to 100 injections were, as a rule, sufficient to prevent or to cure the block. This route should be limited to particular cases only and mainly to those in which the lumbar route is contraindicated. Dihydrostreptomycin rather than streptomycin was given intramuscularly in doses of 10 mg. per kilogram of body weight, with a daily total dose of from 600 to 800 mg. in three divided doses every eight hours. About 8 to 10 gm. of *p*-aminosalicylic acid was also given daily in three divided doses in eight day courses, with a treatment-free interval of 8 to 10 days between each course. When the drug was not tolerated by a few patients, its administration was discontinued. Other adjuvants were iodine, given orally or by injections, and vitamins. Tuberculous meningitis in adults differs from this disease in children in that it has a longer course, spinal block occurs more frequently, and endocrine disturbances, such as excess weight and striae cutaneae distensae, are commoner. A favorable prognosis rests mainly on early diagnosis and early treatment. About 80% of adults with tuberculous meningitis may recover with timely and individualized therapy.

Essential Arterial Spasms.—Essential arterial spasms may occur in widely varying areas in patients who are neither hypertensive nor aged. No visible lesion can be found to explain them. They are most frequent in the extremities, where they produce numbness, cold, or even gangrene; in the retinal vessels, where they lead to loss of vision lasting for some minutes, or to partial vision in which only part of a person or object is seen; and in the cerebral vessels, where they result in fleeting, limited paresis of an arm, a leg, or the tongue. Other symptoms less suggestive of arterial spasm are anxiety, dizziness, perception of arterial pulsations, and abdominal pain. The spasms sometimes follow fatigue or emotional strain, but they may occur without any apparent cause, or, as in most cases, they may be precipitated by exposure to cold. The attacks may occur at frequent intervals, or a single episode may be followed by years of latency; usually, however, there are several attacks separated by intervals of a few months. Some patients will always be affected in the same area; in others, several areas may be involved, simultaneously or successively. None of the patients in the authors' series had arteritis in the affected member. Arterial oscillations and sounds and arterial tension were always normal; the arteries were supple and the heart was sound. Most patients were between 35 and 50 when the first spasms occurred. Differential diagnosis should be aimed at eliminating the symptomatic spasms accompanying various conditions such as Raynaud's disease. Hyperexcitability, either of the arterial wall or of the sympathetic nervous system, may be responsible for the occurrence of essential spasms. Treatment is necessarily symptomatic, consisting of administration of sedatives, vasodilators, and antispasmodics; sympathetic infiltration or sympathectomy may be attempted when the cerebral vessels are involved. The long-term prognosis must be guarded, but the physician should endeavor to relieve the anxiety that often accompanies the condition.

Combination of Three Sex Hormones in Treatment of Menopause.—Administration of combined estradiol, progesterone, and testosterone, intramuscularly or in the form of lozenges to be dissolved under the tongue, to patients with menopausal disturbances produced results equivalent and in some cases superior to those of intensive estrogen therapy, without the undesirable side-effects of synthetic estrogens. Treatment can readily be adjusted to the patient's requirements, and may be continued for long periods without exposing her to the dangers of hormone supersaturation. Hot flashes, severe psychic manifestations, and metabolic disturbances disappear rapidly, and the patient recovers the vitality and balance of character and feeling she had before the menopause. The injectable preparation contains estradiol, 3 mg., progesterone, 20 mg., and testosterone propionate, 25 mg., dissolved in 1 cc. of oil. Injections are needed every one or two weeks at first, but as treatment progresses and the patient's condition improves, the intervals may be lengthened. Patients who have been treated with the combined hormones are unwilling to return to synthetic estrogen therapy, which often produces disagreeable side-effects. Oral administration of lozenges containing ethinylestradiol, 0.005 mg., anhydroxyprogesterone, 5 mg., and methyltestosterone, 2.5 mg., is equally effective and very convenient. The initial dose may consist of from 3 to 5 lozenges daily, but later one or two will usually suffice to maintain the patient in normal neuroendocrine balance. Use of the combined sex hormones in premenopausal patients with normal or subnormal menstrual cycles is not indicated.

*Notes on Lessening of Neurosurgical Operative Insult by Drug Synergy. E. Woringer, J. Schneider, G. Brogly and others.—p. 515.
Total and Subtotal Hemispherectomy. Reflections on Operative Technique. M. Feld.—p. 525.

Use of Autonomic Drugs and Refrigeration in Neurosurgery.—Electroencephalographic studies show that the effect of certain drugs, such as Diparcol (10-[2-diethylaminoethyl]-phenothiazine) and mephenesin (Myanesin), which "potentiate" anesthetics, is both central and peripheral. Their action in producing variations in neuronic excitability is analogous to that of anesthetics and, by the same mechanism, they also affect the higher vegetative centers, causing the body to lose some of its homeostatic reflexes and its ability to react to environmental influences. Gradual refrigeration can then be successfully carried out, and in the resulting state of artificial hibernation postoperative and other disturbances are greatly reduced. Studies of cerebrospinal fluid pressure following administration of the potentiating drugs show no increase in the pressure, which might embarrass a neurosurgeon in opening a dura mater distended by the presence of a subjacent tumor when, as often happens, artificial hibernation must be instituted preoperatively. Application of this procedure to four patients suffering from severe concussion whose death might be expected within six hours and in whom operative intervention would have been useless resulted in immediate improvement. Their symptoms were relieved, consciousness was partially restored, and life was prolonged for three or four days. Patients in poor condition undergoing operations for removal of cerebral tumors and others in whom the proximity of the operative field to the diencephalic centers made postoperative disturbances probable had a remarkably smooth course when placed under hibernation for the first four days. Pulse, blood pressure, and respiration were nearly normal, and the temperature did not rise above 38 C when the hibernation was discontinued. Constant supervision by trained medical personnel is essential for the successful use of this method, which promises to be invaluable in neurosurgery.

*Importance of Some Painful Syndromes of the Extremities in Diagnosis of Pulmonary Cancer. E. Ruggieri.—p. 141.
A New Method for Taking and Studying Tongue Impressions. F. Campeti. —p. 147.
Epidemiology and Prophylaxis of Brucellosis with Particular Reference to Course of This Infection in the Benevento Province. A. Matera. —p. 149.

Pains in Extremities as Only Early Diagnostic Sign of Pulmonary Cancer.—Sometimes the initial clinical phase of cancer of the lung may be represented by pains in the extremities long before respiratory symptoms appear. These pains were the only complaint of 26 of the author's 168 patients in whom cancer of the lung was later found. Ruggieri classifies these pains into three groups. The first comprises those resembling the pains of the syndrome of scapulohumeral periarthritis or Duplay's syndrome. The apex of the shoulder is the focal point and from there the pain radiates along the arms, involving sometimes the elbow, the forearm, the hand, or the fingers. In some cases it may radiate to the anterior region of the thorax as far as the breast and in others along the supraclavicular pit to the neck and the back of the neck. Objective examinations do not reveal abnormalities in the shoulder or in any of the painful areas, palpation and pressure over the focal point do not accentuate the pain, and all passive and active movements are normal. This syndrome was the early diagnostic sign of pulmonary cancer in 15 (8.9%) of the author's patients, and the neoplasm was located near the mediastinum in 12 of them. Differential diagnosis from Pancoast's syndrome is easy, since these patients do not have dystrophy of the muscles of the arm and hand nor Horner's syndrome and the cancer is found near the apex of the lung. It cannot be confused with arthritis, arthrosis, and rheumatic diseases, since in these there is always some functional impairment. Nor can it be confused with periarthritis, since this is always caused by a previous trauma. The second group of pains involves the joints of the elbow, wrist, knee, and ankle of one or all extremities. The intensity of the pain is variable, being more pronounced during humid and rainy days and occurring always during the day. Results of objective examinations of the extremities are always negative, all the movements are normal, the periarticular tissues are not altered, and there is never elevated temperature. Only asthenia of the aching extremities is present. Diagnosis of cancer of the lung was established in five (2.9%) of the author's patients on the basis of this syndrome alone. The third group comprises pains suggesting hypertrophic pulmonary osteoarthropathy. The difference lies in the fact that the radiological picture does not reveal alterations of the articular heads. This syndrome was the only early sign of cancer of the lung in six (3%) of the author's patients. The mechanism of action of these syndromes is still obscure, but since they may indicate cancer of the lung long before any respiratory disturbance appears, a tentative diagnosis of this entity should be made whenever patients complain of pains in the extremities but there are no radiological or objective alterations.

Acute Pulmonary Edema After Penicillin Administration.—A 39-year-old woman with a five year history of vasomotor rhinitis once or twice a month, especially during the spring and fall, and concurrent attacks of dry cough and mild retrosternal pains in the entire thorax, suffered traumatic lesions to the larynx 10 months before admission to the clinic. On that occasion she received 1,000,000 units of penicillin without any side-effect. Later she was given the drug again in an aerosol to control one of the attacks, but the therapy had to be discontinued after the first dose because acute pulmonary edema developed associated with bronchial spasm, increased arterial pressure, tachycardia, and cyanosis. These regressed with administration of morphine, atropine, and camphor. In the following months the asthma-like attacks became more frequent and severer, and the patient, without consulting the physician, gave herself an intramuscular injection of 200,000 units of penicillin. Severe cyanosis, intense cough, at first dry and thereafter productive of a reddish sputum, and loss of consciousness followed. Examination revealed acute pulmonary edema with bronchial spasm and a blood pressure of 160/90 mm. Hg. About two hours after the withdrawal of 400 cc. of blood and the administration of morphine, camphor, atropine, and oxygen, the symptoms disappeared. The reactions to repeated intradermal injections of penicillin were always highly positive. The patient was discharged on March 15, 1951, and has had only one attack since. This occurred after she had been accidentally exposed to patients receiving penicillin in an aerosol.

Studies on Eventual Synergy of Procaine and Cortisone. L. Barilli and R. Rossi.—p. 46.

Streptomycin in Tuberculous Meningitis.—Results are reviewed of streptomycin therapy in 69 children with tuberculous meningitis who were treated at the University of Pisa pediatric clinic from the end of 1947 to the time of writing. All the patients were less than 12 years old. Of the 24 patients who were treated from October, 1947, to August, 1948, only one recovered completely and two recovered after a relapse. These poor results are attributed to the meager knowledge of the drug at that time and to its scarcity. From September, 1948, to February, 1950, more streptomycin became available and therefore the results were better. Of the 19 patients admitted during this period, 5 could not be treated because of their severe general condition that resulted in death a few days later. Eight have recovered and are well; one recovered but died suddenly after his transfer to another institution; and five died. During this period the drug was injected into the cisterna magna. From March, 1950, to the date of writing 26 patients have been treated. Of these, 17 have recovered and are well; 2 had been treated for less than 10 days when death occurred; 2 have improved but are still under treatment; and 5 died. The good results are attributed mainly to the method of administration of the drug and to new adjuvants. At this time the drug was given daily by the lumbar route in doses of 30 to 35 mg. and then 10 to 12 hours later by the suboccipital route in doses of 20 to 25 mg. After the initial improvement, the drug was given by either route until the patient was completely recovered. The therapy was continued, however, and was slowly tapered off within two to three months. During the entire period of treatment streptomycin was given intramuscularly in daily doses of 20 mg. per kilogram of body weight to children older than 2 years and 30 mg. per kilogram of body weight to nursing infants. The treatment period lasted generally for an average of 150 to 180 days. In the entire series of 69 patients a total of 25 children have recovered and remained well; 1 has been well for 3 years, 7 for 2 years, 6 for more than 1 year, and 11 for less than 1 year. Their general condition is good, and development and growth are normal in almost all of them. One patient, who had become deaf during the treatment, is still deaf and is mentally retarded, and a permanent mental deficiency is present in three others. In two of these hydrocephalus had developed during the course of the disease, and one has pronounced sequelae to spastic hemiplegia. Generally the sequelae to the nervous system lesions that occurred during the course of the disease are of little importance and disturbances of motor functions are not too pronounced.

Silent Potts' Disease. B. Blankoff.—p. 279.
*Severe Acute Hemolytic Anemia Following Ingestion of Sodium Ascorbate-Para-Aminosalicylic Acid Solution. M. Lust.—p. 287.

Hemolytic Anemia Following Ingestion of Special p-Aminosalicylic Acid Solution.—Several cases have recently been reported in which the administration of *p*-aminosalicylic acid to children with tuberculous lesions has resulted in severe attacks of acute hemolytic anemia, accompanied by shock, nausea, and occasionally vomiting. Enlargement of the liver and sometimes of the spleen have been noted in most cases, and some patients also have jaundice and azotemia. Erythrocyte fragility is increased during the crisis but returns to normal when it is overcome. The attacks may occur in the first days of the treatment or when the first dose is given, even though the doses are no larger than those usually prescribed. The anemia can be corrected fairly rapidly by one or two blood transfusions and does not recur. All the children in whom it occurred were given a solution of *p*-aminosalicylic acid, sold in ampuls containing in addition a sodium salt of ascorbic acid in a solution of sucrose with sodium saccharinate and flavoring, each 15 cc. ampul containing 3 gm. of *p*-aminosalicylic acid. This solution is easier to administer to children, especially infants, than other forms of *p*-aminosalicylic acid. Anemia followed ingestion of a single ampul in one case; in another, three-fourths of an ampul, or 2.35 gm. of *p*-aminosalicylic acid, precipitated an attack. The children affected are not intolerant to *p*-aminosalicylic acid; some had previously received it in granular form without ill effects. Efforts to find the cause of this complication have been unsuccessful. The possibility of its occurrence should be kept in mind, and blood transfusions should be given at the first sign that it is impending.

*Syndrome of Left Ventricular Overload from Surgical Closure of Patent Ductus Arteriosus. A. Villamil, E. Martínez Zuviría and C. M. Mafia del Castillo.—p. 333.
Fibroma of Ovary. S. L. Sala and N. Santo.—p. 337.
Indications for Surgery in Hyperthyroidism. M. Gallego Tejedor and M. Zaforas Marco.—p. 340.

Left Ventricular Overload After Closure of Patent Ductus Arteriosus.—According to the authors, the electrocardiographic changes observed in the subject of this report have not been previously reported in the literature. They direct attention to the facts that persistence of patency of the ductus results in an increase of the blood volume, the cardiac minute volume, and the work of both ventricles, all of which return to normal after the operation. The electrocardiogram of the majority of these patients is normal before and after the operation. The patient, a woman of 21, developed relatively normally up to the age of 20, when dyspnea and heart palpitation prevented her from working. The electrocardiogram showed a Q wave in the second and third leads and in the V5 lead. The T wave was positive in all leads and the R wave was high in the V1 lead, suggesting increased pressure in the pulmonary artery. The operation was well tolerated. The ductus was short and very wide. The postoperative period was uneventful, and the patient was clinically cured. An electrocardiogram taken 45 days after the operation showed diphasic T waves in the first and second leads and in the left precordial leads. This change lasted for four months after the operation, after which the electrocardiogram became normal. The high R wave in the V lead, which had been observed in the electrocardiogram before the operation, also disappeared together with the abnormal T wave. The authors conclude that overloading of the left ventricle as shown by the abnormalities of the T wave in the electrocardiogram after the operation, could not be related to the newly created conditions of circulation, which were compensated by the diminution of the minute volume after the operation. The operation may have corrected the pulmonary hypertension with consequent control of compensatory hypertrophy of the right ventricle and the development of latent hypertrophy of the left ventricle. Therefore they state that the inversion of T wave after the operation showed overloading that occurred after the relations between the large blood vessels had become normal as a result of the operation.

*Retrolental Fibroplasia. P. Braendstrup and E. W. Flensborg.—p. 317.
Climate in Incubators During Use: Investigation on Normal Variations in Oxygen Content in Incubator Atmosphere During Routine Use. S. Vendel and G. Haglund.—p. 324.
Iron Treatment of Premature Infants. A. Rothe-Meyer and H. Kreutzfeldt.—p. 331.

Retrolental Fibroplasia.—Retrolental fibroplasia was unknown in Denmark before 1949. During the past two years systematic examinations of premature infants in a Copenhagen children's hospital revealed 24 cases of retrolental fibroplasia, and 7 cases have been reported from the Rigshospital's department for diseases of the eye. Of these 33 infants, 8 are permanently blind and 4 have impaired vision; the changes were transitory in the others. Analysis of the material seems to confirm a relationship between the disease and liberal postnatal oxygen therapy and suggests that the oxygen therapy rather than the degree of prematurity may be the decisive factor. Since fibroplasia has been reported in cases without preceding oxygen therapy and only a minority of the children treated with oxygen develop the disorder, an individual factor is thought to be present. The retrolental fibroplasia was not recognized during continuous oxygen therapy but as a rule shortly after cessation of the treatment, which might support the assumption that the disorder is a relative anoxemic retinopathy. Braendstrup and Flensborg caution against liberal oxygen therapy for premature infants and advise administration of oxygen to premature infants only on strict indication, for as short a time as possible, and with gradual reduction of the oxygen percentage.

Symptoms of Acute Porphyria.—The occurrence of acute porphyria with the classical triad of abdominal pain, massive paralysis and dark urine, is reported in three women between the ages of 33 and 54 and in a 40-year-old man. In one of the women, the electroencephalogram demonstrated clearly the diffuse impairment of the central nervous system; a predominant rhythm of 6 to 8 waves per second was observed in the unipolar and bipolar leads from the frontal and parietal areas. There were occasional groups of slower oscillations (4 to 5 per second) occurring symmetrically over both hemispheres. Observations made on the capillaries of the same patient are reported as noteworthy: the capillaries were constricted; the ratio of the arterial to the venous branch was 1:1; many of the capillaries were empty; the flow was stopped for 10 to 30 seconds; and there were no hemorrhages. The excretion of creatine in the urine was determined on several consecutive days in one patient; high amounts up to 324 mg. daily were observed, but there was a drop during menstruation, for which the term "paradoxical creatinuria" is suggested. Various results of urinalysis as reported in the recent world literature on porphyria are presented, and their significance for the clinical diagnosis is discussed. Hormonal relationships in addition to allergic factors are to be considered essential for the course of the acute porphyria. In one of the author's female patients with severe porphyria, a therapeutic trial was made with a proprietary preparation of testosterone propionate in oily solution (Testoviron) in doses of 10 mg. and later on of 25 mg. daily for four weeks. As a result of this treatment, the pareses subsided, abdominal cramps did not recur, and there was an increase in body weight. The urine became clearer with reduced excretion of porphyrin. It is suggested that the transition of the acute disease with its severe neurological symptoms into the latent stage was considerably favored by this treatment.

*Death Following Ingestion of 15 Gm. of Isoniazid. F. W. Scheibe.—p. 283.

Death Following Isoniazid.—A youth, aged 19, with pulmonary tuberculosis took 15 gm. of isoniazid all at once while he was intoxicated. Shortly later he lost consciousness and tonic and clonic convulsions developed, which recurred at varying intervals until death ensued in circulatory failure 16 hours later. The patient never regained consciousness. Necropsy revealed, aside from the pulmonary tuberculosis, vascular turgescence of many organs, particularly of the brain and its meninges. The brain was moreover edematous and swollen and showed perivascular blood extravasation. There was lipoidosis of the liver, heart, and kidneys. The concentration of isoniazid in kidney and liver was 8 and 12 times as high as in the brain. Since cerebral side effects from isoniazid are frequent and severe, the central nervous system must be damaged by much smaller doses than are the parenchymatous organs. The usual therapeutic doses never damage these latter organs. The author feels that the alcohol intoxication, by inducing a general hyperemia, increased the absorption of the isoniazid and thus was a contributing factor in the fatality.

BOOK REVIEWS

Surgery in World War II: The Physiologic Effects of Wounds. By Board for Study for Severely Wounded, North African-Mediterranean Theater of Operations. [Prepared by Historical Division, Army Medical Library], Medical Department, United States Army. Office of Surgeon General, Department of Army. Cloth. $3.50. Pp. 376, with illustrations. Superintendent of Documents, Govern. Print. Off., Washington 25, D. C., 1952.

This book deals with the physiological responses of the body to wounds. The material is taken from surgical records of World War II. Since severe surgical shock associated with trauma is not commonly encountered in medical practice during peacetime, detailed study has seldom been possible. Valuable experimental work on shock has been done with animals since World War I, but there has been little opportunity for study of this serious condition in man. At the outset of World War II, the need for whole blood replacement and for resuscitation was poorly understood.

Proper emphasis is placed on the significance of blood volume, infection, uncontrolled hemorrhage, the site of injury, and limitations of analgesic and anesthetic agents. The material presented is quite remarkable in consideration of the fact that a great amount of it was collected in the open field, at times under direct fire; the data were obtained a few minutes after the injuries occurred. Only by such immediate direct contact with human casualties can such practical information be obtained.

The section that deals with "shock kidney," or lower nephron nephrosis, is especially commendable. This is a study of the clinical records of 60 patients on whom necropsies were performed. Thirty-eight had pigment nephropathy demonstrated histologically; this compared with 22 cases in which this lesion was not present. It was noted that the clinical syndrome or renal insufficiency that follows shock is remarkable for the scarcity and mildness of symptoms. The commonest symptom was drowsiness that slowly deepened into stupor; however, even this at times was absent until death. The commonest sign was edema, either pulmonary or peripheral. The laboratory and blood pressure findings provided more useful criteria.

This book is thought-provoking and will stimulate further study in the response of organs to trauma. It is well written and concisely presented. It is highly recommended to those interested in this field of study, and will no doubt remain an excellent source of reference.

Nutrition in India. By Dr. V. N. Patwardhan, Director, Nutrition Research Laboratories, Indian Council of Medical Research, Coonoor, South India. Cloth. Rs. 15-8. Pp 345, with 28 illustrations. Indian Journal of Medical Sciences, Bombay-4; sole distributors: Hind Kitabs Limited, 261-263, Hornby Road, Bombay 1, 1952.

The name of Col. Robert McCarrison is familiar to those who have studied the history of nutrition. As a medical officer of the British Army in India, McCarrison early in this century began his research on goiter in the mountains of the northwest frontier. He later undertook investigations into deficiency diseases, including his well-known work on beriberi. His activities led to the founding of an institution devoted to research in human nutrition at Coonoor in south India, with the support of the Indian Research Fund Association. After 1922, the institution at Coonoor became the Nutrition Research Laboratories. Dr. V. N. Patwardhan, the writer of this treatise, is its present director.

An important result of the studies at Coonoor has been the enlistment of many young scientists for research in nutrition. They now are engaged by medical colleges and other institutions all over India. Since their research reports, unfortunately, have been published mainly in Indian journals, persons in the United States and Europe who are interested in nutrition will welcome this review. The book provides information on the amazing variety of foods grown in India, their composition and digestibility; basal metabolic rates, which generally are low; and details as to the diets of the various regions. Many of the diets are inadequate in animal protein and vitamins. The results of extensive nutrition surveys are given, as well as accounts of anemia and the prevalent deficiency diseases. Several chapters deal with nutrition in public health practice and with the disturbing problem of overpopulation.

Functional Neuroanatomy. By Wendell J. S. Krieg, B.S. in med., Ph.D., Professor of Anatomy, Northwestern University Medical School, Chicago. Second edition. Cloth. $9. Pp. 659, with illustrations. Blakiston Company (division of Doubleday & Company, Inc.), 575 Madison Ave., New York 22, 1953.

This textbook has been revised to include the results of recent research in the anatomy and physiology of the nervous system, particularly of the wider application of the cathode ray oscilloscope to the exploration of central nervous system pathways. The author has kept the addition of textual material to a minimum but has added many new sketches and three-dimensional drawings.

The anatomy of the various portions of the nervous system is presented from the physiological or functional viewpoint, and in most of the chapters there is a brief discussion of the clinical implications. The text is illustrated with photographs, line drawings, and ingenious three-dimensional sketches. A short chapter that serves as a guide to the student in the laboratory study of the brain and spinal cord and an atlas of sections and slice reconstructions are included. References to the literature are not given in the chapters, but there is a short section with suggestions for further study. There is a brief but adequate index. The material is presented in an interesting and easily read style. All these make the book of great value to the medical student and the neurologist.

Problems of Infancy and Childhood: Transactions of the Sixth Conference, March 17 and 18, 1952, New York, N. Y. Edited by Milton J. E. Senn, M.D., Sterling Professor of Pediatrics and Psychiatry, Yale University School of Medicine, New Haven, Conn. Cloth. $2.50. Pp. 160. Sponsored by Josiah Macy, Jr. Foundation, 16 W. 46th St., New York 36, 1953.

This is a stimulating and sophisticated "infant-centered discussion of early (personality) development." The vivid atmosphere of interchange of experiences and thoughts is dramatically preserved in the literary style of the transactions. The chief contributors are Sibylle Escalona and Katherine Wolf, both of the Child Study Center, Yale University, and Ann Stewart of the Child Health Center, University of Washington. The titles of their contributions are, respectively: "Emotional Development in the First Year of Life," "Observation of Individual Tendencies in the First Year of Life," and "Excessive Crying in Infants—A Family Disease." The other discussants are experts in pediatrics, psychiatry, public health, obstetrics, and experimental clinical science.

The substance of the report is embodied in two to four detailed case studies that each of the chief speakers presented for discussion. Consistent attempts are made to separate descriptive accounts of observed data, "phenomenology by inference," from theoretical conceptions and hypotheses. The method of observation is a sort of dynamic field psychology of the infant's "total situation" or "life space" as it is revealed during repeated visits to the study center. In Dr. Stewart's paper on the colicky baby somatic investigations of various kinds are included, and valuable hints are given to the physician as to how to manage such infants. Attempts are made to predict development and to anticipate neurotic trends.

The case studies are preceded by a fascinating 50-page treatise by Dr. Escalona on what may be termed the world of the infant as seen from within. The method here is purely

---

The reviews here published have been prepared by competent authorities and do not represent the opinions of any official bodies unless specifically stated.

interpretative, and the author often stresses the speculative and imaginative character of her thoughts and "fantasies." These she presents under two headings: "Space, Time, and Reality" and "Social Interaction, Contagion and Communication." The early budding of a dimly sensed "self" that is somehow discerned from a world of "non-self" is exposed in a masterly fashion. This "outer world," for the older infant, remains "idiomatic," animated, and personal, when compared with the objective, realistic, nonself, and public world of the adult. As the infant's world emerges, he experiences the feeling of the uncanny against the background of the familiar, and the birth of conscience is part of his interpersonal primordia. Contacts with young babies are mediated by "contagion," which seems similar to empathy, resonance, or tact. "Contagion" is the archtype of "communication," which the infant later establishes in a more conscious and purposeful manner. Such thoughts ultimately border on philosophical discussions. As Dr. Escalona is well aware, explorations of personal self, human life, existence, world, conscience, moods, and empathy (including "contagion") have been leading themes of philosophers since the 1920's.

L'œsophage en cardiologie: Etude radiologique de l'œsophage dans les cardiopathies congénitales et acquises. Par Marcel Segers et Marcel Brombart. Préface du P^{r} Ch. Laubry. Acta cardiologica, supplementum V. Paper. Pp. 202, with 135 illustrations. Les editions "Acta medica belgica," 64 rue de la Concorde, Brussels, 1952.

In this monograph the authors have reviewed and summarized their systematic studies concerning the roentgenologic aspects of the normal and abnormal relationships of the esophagus to the heart. After a discussion of normal conditions and their physiological variations, the various pathological patterns are systematically described and are illustrated by roentgenograms of excellent technical quality and, in many instances, by instructive diagrams. Particular consideration is given to the types of abnormal esophagrams encountered in mitral disease, in acquired aortic disease, and in congenital anomalies of the aortic arch. The differential diagnosis of these conditions is discussed in the legends to the illustrations as well as in the clear and concisely written text. An extensive bibliography is included. Those who are interested in clinical and, particularly, roentgenologic diagnosis of cardiovascular disease will benefit from reading this booklet.

Pathology of the Heart. Edited by S. E. Gould, M.D., D.Sc., Clinical Professor of Pathology, Wayne University College of Medicine, Detroit. Collaborators: Archie H. Baggenstoss, Associate Professor of Pathologic Anatomy, Graduate School, University of Minnesota, Rochester, et al. Cloth. $25. Pp. 1023, with illustrations. Charles C Thomas, Publisher, 301-327 E. Lawrence Ave., Springfield, Ill.; Blackwell Scientific Publications, Ltd., 49 Broad St., Oxford, England; Ryerson Press, 299 Queen St., W., Toronto 2B, 1953.

This is the first thorough English presentation in book form of pathology of the heart. Dr. Gould has assembled as his collaborators outstanding investigators in the particular subjects assigned to them. By careful editing, duplication of material has been kept at a minimum. Pathology is considered in its broadest sense, so that the book is far removed from a detailed description of morbid anatomy. The relationship of structural changes to abnormal physiology and to the clinical picture is emphasized. A section on normal and abnormal cardiac function was written by Harold D. Green, a cardiac physiologist. The book concludes with a chapter entitled "Clinicopathologic Correlations," written by a clinician, Gordon B. Myers. Congenital malformations are given adequate consideration with regard to their clinical recognition and possible surgical treatment. The etiological approach is indicated by the titles to the various sections, e. g., rheumatic disease, degenerative diseases, nonrheumatic inflammatory diseases, parasitic diseases, injuries, and neoplasms. The appendix contains some useful information on the proper technique in gross examination of the heart at autopsy. Each section is well illustrated. The bibliography at the end of each section is arranged chronologically instead of alphabetically. The text is well written and easy to read. The book should be of considerable value to the cardiologist, the medical student, and the general practitioner.

Treatment of Respiratory Emergencies Including Bulbar Poliomyelitis. By Thomas C. Galloway, M.D., Attending Otolaryngologist, Evanston Hospital, Evanston. Publication number 168, American lecture series, monograph in American Lectures in Otolaryngology, Audiology and Broncho-Esophagology. Edited by Norton Canfield, M.D., Associate Clinical Professor of Otolaryngology, Yale University School of Medicine, New Haven, Conn. Cloth. $3. Pp. 94, with 5 illustrations. Charles C Thomas, Publisher, 301-327 E. Lawrence Ave., Springfield, Ill.; Blackwell Scientific Publications, Ltd., 49 Broad St., Oxford, England; Ryerson Press, 299 Queen St., W., Toronto 2B, 1953.

In this monograph the author attempts by reference to respiratory disorders such as bronchiectasis, laryngotracheobronchitis, and bulbar poliomyelitis to emphasize the need for early recognition of the deleterious effects of respiratory obstruction and anoxia and the need for relief of obstruction before permanent defects result. He outlines briefly the mechanics of obstruction, the pathophysiology of anoxia, factors incident to the care of patients with poliomyelitis, and the proper use of tracheotomy.

One would expect from the title of the monograph to find a discussion of all factors relating to respiratory emergencies, such as care of the upper airway, measures for securing and maintaining ventilation, and the use of endotracheal airways. The emphasis, however, is on tracheotomy, which most physicians will find is indicated in only a small percentage of respiratory emergencies. The section dealing with tracheotomy is complete in description of indications and technique; however, it might be improved by a more detailed description of size and shape of tracheotomy tubes and a discussion of the advantages and disadvantages of high and low tracheotomy.

The "byways" mentioned by the author in the introduction seem to be unnecessary. If the monograph is concerned primarily with treatment of respiratory emergencies, there seems to be little indication for a discussion of the pathogenesis of laryngotracheobronchitis, bronchiectasis or atelectasis, and electrolyte and nutritional balance.

The monograph is beautifully prepared, and the type facilitates reading. Illustrations are few but excellent. The author presents his material in an informal manner with many references to personal experiences; he is especially well qualified to present observations on tracheotomy. The reader may be disappointed if he expects a comprehensive discussion of problems relating to respiratory emergencies. He will, however, find a thorough discussion of the indications for tracheotomy and the technique for its use. The general practitioner will find the monograph useful for meeting the relatively infrequent respiratory emergency requiring tracheotomy.

Clinical Diagnosis by Laboratory Methods: A Working Manual of Clinical Pathology. By James Campbell Todd, Ph.B., M.D., Arthur Hawley Sanford, A.M., M.D., and Benjamin B. Wells, M.D., Ph.D., Professor of Medicine, University of Arkansas, Little Rock. Twelfth edition. Cloth. $8.50. Pp. 998, with 946 illustrations. W. B. Saunders Company, 218 W. Washington Sq., Philadelphia 5; 7 Grape St., Shaftesbury Ave., London, W.C.2, 1953.

This standard textbook and reference on clinical laboratory procedures has been brought up-to-date without any major alterations in the content and chapter subdivisions from the preceding edition. The general excellence of previous editions is maintained. A few changes are found in the chapter on the urine, and some new material has been added to the chapter on blood. The chapter on bacteriological methods has been rearranged to conform to nomenclature and classification found in the sixth edition of Bergey's "Manual of Determinative Bacteriology." The chapter on serologic tests for syphilis also has been revised to conform to the techniques published by the U. S. Public Health Service. Technicians, students, and physicians will appreciate the effort of the authors to provide recognized and uniform methods for the clinical laboratory. As in prior editions, the contents are restricted to established procedures, a feature that makes the book particularly useful as a standard reference. The appendix of data on various standard solutions, tables of normal values, and an outline of laboratory findings in important diseases have been retained. The subject index also indicates the location of illustrations by means of italics. The typography is excellent and apparently free of errors.

Lehrbuch der Krankheiten des Herzens und der Blutstrombahn. Von Prof. Dr. Fritz Lange. Cloth. 71 marks. Pp. 631, with 192 illustrations. Ferdinand Enke, Hasenbergsteige 3, (14a) Stuttgart-W, 1953.

This new German textbook on cardiovascular diseases is a revival of Romberg's book, for many years considered the leading European monograph on the subject. It is printed on good paper and illustrated by many charts, diagrams, roentgenograms, and electrocardiograms, all of excellent technical quality. The text is easily read, is well organized, and contains an ample bibliography. The initial chapter deals with general principles and the anatomy and physiology of the heart and is followed by a section on physical and laboratory diagnosis. There is a systematic and complete description of acquired and congenital heart diseases, including therapy, and there is a similar discussion of diseases of the peripheral vessels. A few confusing mistakes that need correction are: mounting and labelling in figure 127; misinterpretations of electrocardiograms in figure 91 b, page 122; inadequate legends to figures 135 and 136; and conflicting statements concerning the effect of digitalis on coronary flow on pages 312 and 317.

From the viewpoint of the American reader, certain concepts and general statements may appear unsatisfactory and obsolete. For example, no emphasis is given to the central role of disturbed electrolyte balance in the pathogenesis of congestive failure, and the low salt syndrome in the course of mercurial diuresis is not mentioned. The concept of collagen diseases is ignored, and the respective entities are dealt with mainly in the chapter on peripheral vascular diseases. No mention is made of the principal difference in the treatment of paroxysmal and chronic forms of auricular tachycardia. Procaine amide (Pronestyl) hydrochloride is not mentioned in the recommended therapy of ventricular tachycardia with intravenous morphine. The author's viewpoints on spa therapy of heart disease and the use of leeches are also obsolete. In dealing with the pathogenesis of essential hypertension, the author gives preference to the concepts of Volhard and Julius Bauer.

In general, however, the present author, one of Romberg's disciples, succeeded well in reviewing the vast literature, accumulated since 1925, and in correlating advances in clinical cardiology with the basic ideas of the traditional German approach to clinical diagnosis and teaching.

Fanconi and Wallgren's Textbook of Pædiatrics. Edited by W. R. F. Collis, M.A., M.D., F.R.C.P., Physician, National Children's Hospital, Dublin. Translator and co-editor: E. Kawerau, M.B., M.Sc., A.R.I.C. [Originally published under title Lehrbuch der Pädiatrie by Benno Schwabe & Co., Basel.] Cloth. $19.50. Pp. 1104, with 441 illustrations. Grune & Stratton, Inc., 381 Fourth Ave., New York 16, 1952.

This is an English edition of the original German textbook, "Lehrbuch Der Pediatrie." The book contains contributions from 19 well-known European pediatricians who, as far as possible, confine themselves to their own particular specialties and express their own ideas.

There are 33 chapters, including a chapter on tropical conditions in childhood and a synopsis of medical treatment. There is considerable revision of the German text, bringing up-to-date the section on antibiotics and including fresh material in many chapters.

While the book is comprehensive and detailed, it is somewhat deficient in discussion of the newer remedies, particularly the broad spectrum antibiotic drugs. In treatment of Hemophilus influenzae meningitis, for example, only the sulfonamides and streptomycin are recommended. While most therapy seems similar to that practiced in the United States, measures such as mustard poultices in the treatment of bronchiolitis are obsolete. Another serious deficiency is the lack of adequate and up-to-date references. Despite these drawbacks, the book contains considerable valuable information and excellent black and white and colored photographs. The type, paper, and binding are excellent; however, except for the illustrations, the book scarcely measures up to American textbooks.

Roentgen, Radium and Radioisotope Therapy. By A. J. Delario, M.D., Head of Therapeutic Radiology, St. Joseph Hospital, Paterson, N. J. Cloth. $7.50. Pp. 371, with 65 illustrations. Lea & Febiger, 600 S. Washington Sq., Philadelphia 6, 1953.

The title of this book is somewhat misleading in that there is minimal coverage of therapeutic aspects, the greater portion of the volume being devoted to the physical foundations of ionizing radiations. Concerning roentgen therapy, there is merely a cataloging of diseases amenable to treatment, without reference to technique of treatment planning or any of the other factors involved. It is also unfortunate that the author devotes a disproportionate amount of discussion to the erythema dose, since the tumor dose is the accepted unit of choice. There is little reason to expect that this volume will supersede or supplement standard works on roentgen therapy.

Radium therapy is covered in one chapter, the material consisting of the usual distribution rules, charts, and tables necessary for dosage calculations. Since the subject has been covered in more detail in well-known standard works, the present contribution is not significant. The chapters on radioactive isotopes are up-to-date and contain much useful information in condensed form. The presentation should prove useful as a general introduction for the interested student.

There are no sound physical foundations for the theory of the nature of roentgen rays as promulgated in this work. This theory postulates that the rays are propagated similarly to sound waves and that the neutrinos of the atmosphere vibrate and conduct the electromagnetic waves. Similar liberties taken with basic physical laws are found in isolated examples throughout the volume. There are, however, many useful charts and tables, compiled from many sources and covering the entire range of subjects. These may be used for reference by the student of radiation therapy. In addition, recent developments, such as radiation from atomic fusion and fission, are adequately treated.

Speech and Hearing in Communication. By Harvey Fletcher, Ph.D. Bell Telephone laboratories series. [Based on "Speech and Hearing," 1929.] Cloth. $9.75. Pp. 461, with 246 illustrations. D. Van Nostrand Company, Inc., 250 Fourth Ave., New York 3; 25 Hollinger Rd., Toronto; Macmillan & Company, Ltd., 10 St. Martin's St., Leicester Sq., London, W.C.2, 1953.

Physics of sound, as applied to speech and hearing, was advanced considerably by the publication of the first edition of "Speech and Hearing" in 1929. Written by a physicist who had devoted 15 years to research in the transmission of sound at the Bell Telephone Company laboratories, the book proved to be an authoritative source of information on acoustics and one on which much of the later research in communications was based. This new book of the same name, based on the author's earlier work, contains the most recent information on acoustics. The author discusses the physics of the speaking and hearing mechanisms of the human being. The fundamentals of acoustics and methods of calculating articulation scores are also presented. A new method for the calculation of perception of speech and a method for computing per cent hearing loss are proposed. The book deals extensively with the mathematical approach to acoustical problems. Although the technical discussions can be understood by the physicist, engineer, or mathematician, the general practitioner, unless he is well versed in mathematics, may find the book difficult reading. On the other hand, physicians who are interested in hearing and speech will find the book extremely valuable.

Die Konservierung von Knochengewebe für Transplantationen. Von Hans Roth, Oberarzt der chirurgischen Universitätsklinik Basel. Cloth. $11.60. Pp. 222, with 147 illustrations. Springer-Verlag, Mölkerbastei 5, Vienna 1, 1952.

This attractive, well-written, and richly illustrated book reviews past experience on bone transplantation and contributes new data. The author believes that at present the best method for preservation of donor material is at -12 to -20 C under liquid petrolatum. The bibliography is comprehensive, representative, and up-to-date, and there are author and subject indexes. The book is recommended to orthopedic surgeons and to all others concerned with problems of tissue transplantation.

The Control of Communicable Diseases. By Hugh Paul, M.D., D.P.H., Medical Officer of Health, Smethwick County Borough, Staffordshire, England. With foreword by G. S. Wilson, M.D., F.R.C.P., D.P.H., Director of Public Health Laboratory Service. Cloth. 55/-. Pp. 526, with 30 illustrations. Harvey & Blythe, Ltd., 212 Shaftesbury Ave., London, W.C.2, 1952.

This volume is designed, according to the author, for the needs of physicians, whose "importance in the realm of the control of communicable diseases can scarcely be exaggerated." The author has selected the infections of major concern to British physicians and has attempted to present a critical appraisal of their epidemiology and control. Only minor attention has been given to infections not endemic in the British Isles. The volume is rich in historical data, which are so commonly omitted from books of this type. Special attention has been given to the collection of statistical information on the incidence of these diseases and to discussion of the administrative procedures currently required in Great Britain. It is thus a valuable compendium of information that is otherwise widely scattered.

The critical student of epidemiology will, however, question certain parts of the volume. Without denying the public health importance of cancer, he may question discussion of it in a book on communicable diseases. The author makes sharp distinctions between scarlet fever and streptococcic sore throat and virtually neglects the significance of type differentiation in the epidemiology of streptococcic infections. Dust is emphasized in the spread of such infections, and little attention is given to the significance of direct contact with unrecognized ambulatory cases. The author neglects the carrier as a source of food contamination in the spread of typhoid and emphasizes water contamination. One can hardly agree that "as a general rule in typhoid fever one should look for a carrier who has contaminated water, and in paratyphoid, for one who has contaminated food," or that in milk-borne outbreaks the commonest method of contamination "is probably the use of infected water for washing the milk utensils, or for cooling them." The statement that the room that has been occupied by the typhoid patient "should be sprayed with either a carbolic or hypochlorite disinfectant," is surprising. If these statements are correct, the epidemiology of typhoid and the requisite control practices in England differ strikingly from those in the United States. The critical reader will find many other statements to which he may take exception. These many controversial aspects do not destroy the value of the book for the advanced student or the critical reader but limit its usefulness as a text or as a general reference volume.

Diseases of the Heart and Arteries: Anatomical and Functional Disturbances of the Circulation, Treatment. By George R. Herrmann, M.S., M.D., Ph.D., Professor of Medicine, University of Texas, Galveston. Fourth edition. Cloth. $12.50. Pp. 652, with 219 illustrations. C. V. Mosby Company, 3207 Washington Blvd., St. Louis 3, 1952.

Through successive editions, this book has grown from a small handbook designed for the medical undergraduate and the busy physician to a massive textbook. This is somewhat unfortunate, because there are many good textbooks on diseases of the heart but few concise manuals on the subject. Dr. Herrmann, who is an authority on cardiovascular disease, does a competent job, but his problem as to selection of material is evident. Such great strides are being made in this field that even such a large book can deal only briefly with many important aspects of cardiovascular disease. Omission of the section on peripheral vascular disease and the section on military cardiovascular examinations would not in any way detract from the value of the book and would save considerable space that could be used for other important material on heart disease. For instance, the recent important advances in cardiac surgery should be described in detail, and a more complete discussion of the mechanism of heart failure would also be desirable. In general, the book represents a comprehensive survey of present knowledge on cardiovascular diseases and is, therefore, a good reference book for the practicing physician. Many illustrations, charts, and figures accompany the clearly written text.

Modern Treatment: A Guide for General Practice. By fifty-three authors. Edited by Austin Smith, M.D., Editor of Journal of American Medical Association, and Paul L. Wermer, M.D., Secretary, Committee on Research, American Medical Association. Cloth. $20. Pp. 1146, with 13 illustrations. Paul B. Hoeber, Inc. (medical book department of Harper & Brothers), 49 E. 33rd St., New York 16, 1953.

Books on therapeutics have come to take two forms; either the small manual for quick reference and handy carrying or the large and comprehensive volume for more serious and protracted study. This book is a highly competent example of the latter type. It contains, in detail, both the background and the practical application of all ordinary, nonsurgical therapy.

The book is introduced by a general chapter on the patient-physician relationship, written by the editors. This is a surprisingly instructive consideration of a number of topics not ordinarily discussed together. Of particular interest are the sections on ethics and legal restrictions on drugs and other treatments and on clinical research and the evaluation of new drugs. The next four chapters consider general factors in the treatment of disease; namely, pharmacological principles, immunology, chemotherapeutic agents, and general principles in infections. The major portion of the book is a consideration of individual diseases, beginning with bacterial infections and ending with poisonings. Unlike most large books on therapy, this one includes interpolated chapters on relevant aspects of general problems such as pain mechanisms and the fundamental explanation of shock. Medical readers at every level may be assured of interesting reading and reliable answers to their therapeutic problems.

The book is handsome, though heavy, and the text is superbly designed and printed. The double columns facilitate reading. Some readers will be bothered by the paucity of references, but, since the authors are authorities in their fields, this may be largely overlooked. The prevalent use of trade names of drugs may also be criticized. Altogether, the book is a modern classic, and all concerned in the extensive project are to be congratulated.

The Essentials of Medical Diagnosis: A Manual for Students and Practitioners. By Rt. Hon. Lord Horder, G.C.V.O., M.D., F.R.C.P., Extra Physician to H. M. the Queen, and A. E. Gow, M.D., F.R.C.P., Consulting Physician, St. Bartholomew's Hospital. Second edition revised with assistance of Ronald Bodley Scott, M.A., D.M., F.R.C.P., Physician to H. M. Household. Cloth. $6. Pp. 462, with 50 illustrations. (William Wood book), Williams & Wilkins Company, Mount Royal and Guilford Aves., Baltimore 2, 1953.

The authors of this book need no introduction to members of the medical profession. The senior author is known not only for his medical ability but for his determination to preserve freedom in medical practice. It is not surprising then that these writers should prepare a book that wastes no words and yet is easily read and understood. It is offered as a manual for students and practitioners and certainly will be recommended by those who become familiar with it. As an office reminder or bedside companion, this book will carry the reader from one medical problem to another with a degree of interest normally reserved for less seriously written books.

Bodily Physiology in Mental and Emotional Disorders. By Mark D. Altschule, M.D., Assistant Professor of Medicine, Harvard Medical School, Boston. Cloth. $5.75. Pp. 228. Grune & Stratton, Inc., 381 Fourth Ave., New York 16, 1953.

This book is interesting because of the author's analysis of the data and ideas found in an already overwhelming literature. Each bodily system is discussed separately and thoroughly. There are 251 references on the subject of blood alone, with corresponding numbers in other chapters. The author maintains that the undisciplined manner in which the "jungle of mental disorder" has been explored in the past is the reason for the present confusion. Psychiatry, he believes, must get beyond its "exclusive preoccupation with superficially acceptable conclusions." This book is well written, indexed, and documented.

Clinical Neurology. By Frank A. Elliott, M.B., Ch.B., F.R.C.P., Assistant Physician to Charing Cross Hospital, London, Brodie Hughes, Ch.M., F.R.C.S., Professor of Neurosurgery, University of Birmingham, Birmingham, England, and J. W. Aldren Turner, M.A., D.M., F.R.C.P., Neurologist to Saint Bartholomew's Hospital, London. Edited by Frank A. Elliott. Cloth. $10. Pp. 751, with 8 plates. Paul B. Hoeber, Inc. (medical book department of Harper & Brothers), 49 E. 33rd St., New York 16, 1953.

This English textbook by two competent neurologists and a neurosurgeon is designed for postgraduate students of neurology. Since it is not intended for the beginning student or the senior practitioner, the book does not contain descriptions of rare disease and controversial methods of treatment. The neurosurgeon has written an excellent section on tumors and injuries. The style is admirable, the contents are informative and adequate, and the whole book is an excellent treatise compiled by authors of wide experience. There is a full, skillfully arranged index, and the format of the book is particularly pleasing. There are references to the most important literature through 1950. American readers may not be familiar with such terms as "Both or Bragg-Paul respirator," but this is a minor point. The book in general is sound and might well find a place in the United States as a textbook for postgraduate study.

A Short Practice of Surgery. By Hamilton Bailey, F.R.C.S., F.A.C.S., F.I.C.S., Senior Surgeon, St. Vincent's Clinic and Italian Hospital, London, and R. J. McNeill Love, M.S., F.R.C.S., F.A.C.S., Surgeon, Royal Northern, Mildmay Mission, and Metropolitan Hospitals, London. Ninth edition. Cloth. $12.50. Pp. 1254, with 1234 illustrations (pathological illustrations by L. C. D. Hermitte, M.B., Ch.B., Pathologist, Royal Infirmary, Sheffield). Williams & Wilkins Company, Mount Royal and Guilford Aves., Baltimore 2; [H. K. Lewis & Co., Ltd., 136 Gower St., London, W.C.1], 1953.

The first edition of this book was published more than 20 years ago. Time alone does not account for its popularity; the way the book is written, the illustrations, and the subjects encompassed make this book welcome to many. It is crammed with a wealth of material and is presented so that everyone can understand it. The book is well-illustrated with colored and black and white figures to a surprising degree for such a comparatively small volume.

How to Prepare for Marriage. By John Douglas, M.D., and Elizabeth Hardy, R.N. Cloth. $2.50. Pp. 135, with illustrations. Pageant Press, 130 W. 42nd St., New York 36, 1952.

Excellent premarital information and advice are contained in this small volume, but there is a general consideration of douching that may not find favor with all physicians. The discussion about "cleansing" douches should be qualified with the recommendation that before such procedures are instituted a physician should be consulted, as is mentioned in the introduction to the discussion of douches in treatment of disease. A chapter containing advice for men is especially well done, as is the one on solution of problems that are likely to develop after the honeymoon. There are concise but adequate chapters on the male and female genitalia. An epilogue suggests that readers who have problems not discussed in the book send them to the authors; again, consultation with a local physician should have been recommended.

Bedside Diagnosis. By Charles Seward, M.D., F.R.C.P., Honorary Physician, Royal Devon and Exeter Hospital, Exeter, Devonshire, England. With foreword by Sir Henry Cohen, M.D., F.R.C.P., Professor of Medicine, University of Liverpool, Liverpool, England. Second edition. Cloth. $3.50. Pp. 380, with illustrations. Williams & Wilkins Company, Mount Royal and Guilford Aves., Baltimore 2; E. & S. Livingstone, Ltd., 16 and 17 Teviot Place, Edinburgh 1, 1952.

This book, which was begun less than 10 years ago in India, richly deserves the foreword by England's renowned Sir Henry Cohen. It is brief but is sufficiently detailed so as to make the passages clear to the readers; it is written simply and yet not insultingly so. This is the type of book that the student will welcome and the physician will use through the years of practice. Unfortunately, there are no pictures, as are often found in other manuals of this type, but this does not detract from the value of the book. The author might well consider illustration of a future edition.

Practical Blood Grouping Methods: A Manual of Immunohematology. By Robert L. Wall, M.D. Publication number 122, American Lecture Series, monograph in Bannerstone division of American Lectures in Hematology. Edited by Russell L. Haden, M.D. Cloth. $5. Pp. 175. Charles C Thomas, Publisher, 301-327 E. Lawrence Ave., Springfield, Ill.; Blackwell Scientific Publications, Ltd., 49 Broad St., Oxford, England; Ryerson Press, 299 Queen St., W., Toronto 2B, 1952.

According to the paper cover of this volume, the book contains "the latest information on all aspects of immunohematology." Anyone familiar with the latest developments in blood grouping knows that it is hardly possible to cover all aspects of the subject in 150 small pages. As a result, the treatment is superficial and hardly more detailed than that found in some of the better texts on clinical pathology. The book has very few tables and no figures. The author's handling of some subjects is far from authoritative. The presentation is not profound, as shown by the description of the antiglobulin test, the very brief chapter on recent advances, and the inadequate discussion of Rh nomenclature. The book is not recommended for those who wish detailed information on the subject.

Advances in Biological and Medical Physics. Volume III. Edited by John H. Lawrence and C. A. Tobias. Cloth. $8. Pp. 368. Academic Press, Inc., 125 E. 23rd St., New York 10, 1953.

This volume contains seven chapters, two of which deal with radioactive isotopes, two with molecular biophysics, one with ultrasound, and two with new developments in microscopy. It is lucidly written, liberally illustrated, and is provided with subject and author indexes and a bibliography. The book cites so many examples of the magnificent achievements of modern physics that it is almost discouraging to a medical reader. Baffled daily by unsolved problems like bursitis and lymphedema, one wonders at the apparent ease with which the physicist develops scanning x-ray microscopes or obtains color-translated ultraviolet photomicrographs. The physicist has a rich store of well-demonstrated facts compared with the conflicting data of physiology, and his results seem more permanent than the physician's temporary victories over disease. This book is, however, an inspiring presentation of the research that is being done for eventual use in the relief of suffering.

Women Are My Problem: The Autobiography of an Obstetrician and Gynecologist. By J. L. Bubis, M.D., F.A.C.S., Consultant in Obstetrics and Gynecology, Mt. Sinai Hospital, Cleveland. Cloth. $3. Pp. 223, with illustrations. Comet Press Books, 11 West 42nd St., New York 36, 1953.

The first part of this book is devoted to the life history of the author's family. It is human, interesting, and a tribute to the author's parents, who prepared him for his future and gave him his ideals. The latter part of the book deals chiefly with Bubis' hard struggle to have obstetricians and gynecologists accept his ideas about immediate postpartum repair of lacerations. R. S. Kline and Bubis coined the term puerperal gynecology for this type of surgery, which the medical profession has been slow to accept. Bubis wrote a book on the subject, and only about half of the first edition of a thousand copies was sold; however, he has the satisfaction of having a recent chairman of the Section of Obstetrics and Gynecology of the American Medical Association devote his address to puerperal gynecology. The book is ably written with sincerity and in places with pugnacity. Since it is for the laity, most of the case reports could have been omitted.

Symptoms and Signs in Clinical Medicine: An Introduction to Medical Diagnosis. By E. Noble Chamberlain, M.D., M.Sc., F.R.C.P., Senior Physician, Royal Southern Hospital, Liverpool. Fifth edition. Cloth. $8. Pp. 480, with 354 illustrations. Williams & Wilkins Company, Mount Royal and Guilford Aves., Baltimore 2; John Wright & Sons, Ltd., 42-44, Triangle West, Bristol 8, England, 1952.

This excellent book, which is intended to be an introduction to medical diagnosis, was first published in 1936. Its success is evident from the fact that a fifth edition was issued in 1952. Simply written and excellently illustrated, it provides in compact form a wealth of material for the student and practitioner. It is the sort of book the physician likes to have readily available by his desk and at his bedside.

QUERIES AND MINOR NOTES

SAFETY OF MILK PRODUCTS IN EUROPE

To the Editor:—*Many persons who are going to Europe for vacations have asked about the safety of eating milk products in the European countries. While it is possible to ask whether the milk has been pasteurized, it is not always possible to determine whether pasteurized milk has been used in ice cream and the various cheeses. Is the ice cream available in Europe made of pasteurized milk? Is there any hazard in eating cheese made of raw milk?*

M.D., Texas.

Answer.—In this country, ice cream is prepared by the mixing together of the various ingredients, after which the mixture is pasteurized and homogenized. Information is not available as to whether the ice cream mixture in all foreign countries is subjected to pasteurization. In England, it is given essentially the same treatment as it is in this country. Unless it is definitely known that the ice cream mix is pasteurized and subsequently processed in a sanitary manner, it would probably be well to forego eating it while in Europe. Cheese may be made from either pasteurized or raw milk. If made from raw milk, the United States Food and Drug Administration stipulates a minimum aging period under conditions of controlled humidity and temperature. This is usually at least 60 days. Unless cheese is known to have been made from pasteurized milk or to have been properly aged, it would be unwise to use it.

MICROCEPHALY AND HEREDITY

To the Editor:—*A patient's brother-in-law has been married twice and with each wife has had a son and a daughter. Both girls were microcephalic. Their physician states that this is an hereditary affair and that under no circumstances should any males of this family have children. Although my patient's husband, one of the brothers, has fathered three boys and one girl, all normal, she is concerned that her male children may transmit the microcephalic characteristic.*

William R. Galeota, M.D., Kerkonkson, N. Y.

This inquiry was referred to two consultants, whose respective replies follow.—Ed.

Answer.—There seems to be a misconception of the type of heredity involved. Were the characteristic of microcephaly sex-linked, it would usually be expressed in males and transmitted by females, just the reverse of the situation described above. The extensive literature indicates that microcephaly depends, for its expression, on the presence of the double dose of a recessive gene, not sex-linked. While the frequency of true microcephaly is only about one in 50,000 births, persons carrying the single dose of the concealed recessive gene are relatively numerous, almost one in every 100 persons. It is a remarkable, though entirely possible, coincidence that both wives of the patient's brother-in-law carried this particular recessive characteristic.

There is no reason why the normal members of this family should not have children. It has been shown that every person carries one or more deleterious recessives in the concealed condition and is, therefore, in as dangerous a position as the members of the above-mentioned family.

Answer.—Microcephaly is relatively infrequent. Few studies of significant scope, dealing with the familial frequency of this condition, are on record. As a result, little is known regarding its mode of hereditary transmission. There is evidence to indicate that microcephaly is due to a single recessive gene, but evidence that it is a sex-linked condition is insufficient. The chance that any physical abnormality will recur in a family depends on a number of factors. These include the frequency of the condition in the population, the extent to which persons in a family, who do not exhibit the trait, may be carriers of the gene for the trait, the closeness of the relationship between the member of the family having the condition and other members of the family, and whether a member of the family in which the trait has appeared is a carrier and happens to marry another carrier.

In view of our lack of knowledge regarding the above factors in the general population and in the family in question, no definite statement can be made with respect to the chance that microcephaly will reappear in the family in question. On the basis of present knowledge, there would seem to be very little chance that the patient's sons or daughter would be likely to have a child exhibiting microcephaly.

HYPOTHYROIDISM

To the Editor:—*I am treating a patient, aged 24, for a mild degree of hypothyroidism. She is comfortable when receiving 2 to 3 grains (0.13 to 0.19 gm.) of thyroid daily. She asks whether she will ever be able to stop thyroid medication, without which her basal metabolic rate is persistently about -20%. Her protein bound iodine level is 2 mcg. per 100 cc., and her blood cholesterol level is over 300 mg. per 100 cc. She does not have the appearance of a patient with classical myxedema; however, when she is without thyroid medication she is less alert, fatigues easily, and has a feeling of not being well. Placebo substitution for the thyroid extract does not control her symptoms. Can she expect spontaneous remission after a given period of treatment? Does the situation parallel that in spontaneous remission in other endocrinopathies, such as diabetes mellitus? Does prolonged administration of thyroid suppress any function of the pituitary in such a patient?*

M.D., New Jersey.

This inquiry was referred to two consultants, whose respective replies follow.—Ed.

Answer.—A spontaneous remission of some degree in this patient is possible, not in relation to the length of treatment but to the menopause, when there is sometimes an increase in thyroid activity; however, this is the exception rather than the rule. Spontaneous remission in classical myxedema is rare. The situation does parallel that relating to spontaneous remission in other endocrinopathies. Administration of thyroid suppresses the secretion of thyrotropic hormone by the anterior pituitary gland, but, after cessation of even prolonged administration, the anterior pituitary gradually escapes from the inhibition.

Answer.—The criteria for the diagnosis of hypothyroidism in this patient are largely subjective. The only objective findings are slight depression of the basal metabolic rate to a level of -20% and an increase in the serum cholesterol level to 300 mg. per 100 cc. It is probable that hypothyroidism, if present, is secondary to hypopituitarism, and a careful search should be made for other evidence of pituitary insufficiency. If hypopituitarism is present, the correction of the hypothyroidism is only one phase of the treatment and will only partially correct the patient's disturbance. Hypothyroidism rarely disappears spontaneously, regardless of whether it is primary or secondary in type. Prolonged administration of desiccated thyroid may cause some suppression of pituitary function if it is given in excess. When given in quantities sufficient to correct hypothyroidism, it does not suppress pituitary function.

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any official bodies unless specifically so stated in the reply. Anonymous communications and queries on postal cards cannot be answered. Every letter must contain the writer's name and address, but these will be omitted on request.

PURPURA SIMPLEX

To the Editor:—*What is the cause of a tendency to bruise readily, in the absence of overt disease? This is especially noticeable in the proximal extremities and worse when the muscles are held tensely.*

Edward Dengrove, M.D., Asbury Park, N. J.

Answer.—Purpura simplex is the term applied frequently to the disease complex to which the symptom described in the query belongs. It includes single or multiple mild attacks of purpura without a clear cause, although allergic and/or hormonal factors are vaguely blamed. One condition belonging to the syndrome is referred to as simple, easy bruising. It affects women primarily, beginning sometimes in early childhood and persisting throughout life. The skin of these patients is usually fair, thin, and sensitive to solar and chemical irritants. The lesions are located primarily on the arms and legs. Vulnerability of capillary endothelium to physical or chemical trauma is probably a responsible factor. Pituitary and thyroid dysfunction are also suspected. There is a tendency to menstrual disorders and to a low basal metabolic rate. Laboratory tests applicable to the study of hemorrhagic disorders are usually normal. Improvement has been reported following administration of thyroid.

The fact that "holding muscles tensely" aggravates the bruising tendency places this patient's condition in a group of conditions known as mechanical purpura. This is seen in otherwise normal persons in an area of the body subjected to a sudden increase in venous pressure. The hemorrhage is due to mechanical rupture of the capillaries. Here, also, the laboratory tests are normal. A third condition in which hemorrhages occur in the extremities, primarily in women, frequently appearing for the first time at menopause, has been described as hereditary familial purpura simplex. In this condition, the test for capillary fragility may give positive results. A hereditary weakness of capillaries is held responsible. There is no specific therapy available for these conditions, except for the previously mentioned use of thyroid in purpura simplex. If operation is necessary, the bruising tendency is not a contraindication as a possible cause of hemorrhage, because these patients have no abnormal bleeding tendency. It is important to recognize the true nature of the condition and not to confuse it with other more serious types of purpura. It is most important to exclude thrombocytopenic purpura. A platelet count will help to establish the diagnosis.

DRUG THERAPY OF PEPTIC ULCER

To the Editor:—*In treatment of a duodenal ulcer is there any contraindication to the use of both methantheline (Banthine) and adiphenine (Trasentine) with phenobarbital? A patient has had a duodenal ulcer for a year, with little if any roentgenographic change. He has had no ulcer discomfort since he has been taking methantheline, but the ulcer fails to heal. Could this be due to the fact that he has also been receiving adiphenine with phenobarbital because of pylorospasm? Are the two drugs in any way antagonistic to each other?*

M.D., California

Answer.—There is no contraindication to the combined use of methantheline and adiphenine with phenobarbital. Methantheline, atropine, and phenobarbital are commonly used in the treatment of peptic ulcer. Lack of healing is most likely due to the fact that sufficiently large doses of these drugs are not used and ulcer management of the rigid type has not been carried out. The average peptic ulcer of the duodenum should heal within two to four months, unless a patient has the complications of ulcer or the ulcer has an arteriosclerotic base and is large enough to prevent healing. If the ulcer does not heal within two to four months with rigid management and the patient shows the crater on repeated roentgenologic examination, he should be treated surgically rather than continued on conservative medical management. When a patient has a deformity of the duodenal bulb, it does not necessarily indicate that there is activity in the ulcer bed. A spasm may be relieved when the ulcer is healed, but the superficial scarring and irregularity of the bulb may persist long after the ulcer is healed. Only by compression techniques can it be determined whether one is dealing with an active peptic ulcer.

CONVULSION IN INFANT FOLLOWING INJECTION OF VACCINE

To the Editor:—*About 16 hours after an 8-month-old infant received his fourth monthly 0.5 cc. injection of combined diphtheria-tetanus toxoids (alum-precipitated) and pertussis vaccine, he suddenly had a convulsion, with jerky quick movements of all four extremities repeated rapidly for two to three minutes. The child then became limp, pale, and unresponsive and was in a state of collapse. His eyes did not react to light, and at times his eyeballs wandered meaninglessly. His respirations were slow and shallow and his lips slightly cyanotic. I administered 0.1 cc. of aqueous epinephrine in 1:1,000 dilution intramuscularly and 0.1 cc. of a solution containing 0.25 gm. of aminophylline per cubic centimeter. The child responded to the second injection with a cry. I inserted a rectal suppository containing 75 mg. of aminophylline. The child became progressively more responsive and, though irritable, took an 8 oz. (240 cc.) bottle of milk containing 1 teaspoonful of chloroprophenpyridamine (Chlor-trimeton) maleate syrup. Three hours after the first seizure, he had severe shaking of all four extremities lasting 15 seconds, apparently precipitated by a sudden noise. Because of continued agitation, I gave 0.06 gm. of pentobarbital sodium intramuscularly, followed by 15 mg. of phenobarbital orally by dropper every 3 hours for the next 12 hours. The next day the child took only liquid foods and was sleepy but looked normal. All medication was stopped. Apparently there are no localizing neurological signs. Three days later the child was eating well and was normally active. I intend to vaccinate this child for smallpox at 11 months of age. Is there any danger in this procedure?*

Joseph P. Miranti, M.D., Toledo, Ill.

Answer.—Reactions such as that described have been attributed to pertussis vaccine. Instances have been reported (Byers, R., and Moll, F.: *Pediatrics* 1:437, 1948) in which encephalitis developed, and in some cases death ensued. In a review of the subject, Toomey (*J. A. M. A.* 139:448 [Feb. 12] 1949) found that sometimes there was a history of mental deficiency in a relative of the patient. The foregoing comments explain the diagnosis in your case. The treatment administered was proper and proved satisfactory. If booster doses are to be given, it is advisable to withhold them until the child is at least two years old. It may be wise not to administer any additional doses of pertussis vaccine. If a booster of any antigen is injected, it should be given in divided doses, beginning with 0.1 cc. Unless there is an instance of known exposure to smallpox or smallpox is existent in the community or the family proposes to go on an extended journey, it would be preferable to postpone vaccination until shortly before the child enters kindergarten or school. Before giving a booster dose it may be prudent to do a Maloney test for toxoid sensitivity (inject intradermally 1/10 cc. of 1:20 dilution of the toxoid, and read the result at the end of 48 hours. A neurological follow-up examination would be a proper procedure; however, it does not seem likely that any permanent damage has been caused by the immunizing agents thus far administered.

RINGWORM OF SCALP

To the Editor:—*An x-ray epilation of the scalp for ringworm was done and a poor result obtained. How long a period of time should be allowed to elapse before this is repeated with a larger dosage?*

M.D., New Jersey.

Answer.—One should wait for at least six months to be certain that the first epilating procedure did not produce any areas of permanent alopecia. Then, too, it is well not to rely on x-ray epilation alone to effect a cure. It should be supplemented by manual epilation of hairs under the Wood's light and the use of topical applications. The whole procedure of x-ray epilation is an exact one, with a precise dosage, and should be administered by one experienced not only in the technique but also in the mycological and clinical characteristics of the disease.

FIBERGLAS

To the Editor:—*A woman, aged 41, started to work with Fiberglas in February, 1951, and in June an eruption of the fingers, hands, forearms, and wrists developed, which subsequently became generalized. She was hospitalized for six weeks. Two weeks after discharge from the hospital and away from her work, she was hospitalized again for an exacerbation of the eruption, which again improved. Patch tests with Fiberglas gave a severe positive reaction. Positive results also were obtained with other materials in a new job assigned to her. Since the onset of the eruption she has worked only three days, this being done away from the department where she worked originally. On the third day she again had an exacerbation of the eruption and had to stop work. Because of persistent vomiting, she was seen by an internist, whose impression was "acute anxiety reaction secondary to her dermatitis." In May, 1952, she was examined by a dermatologist for the Industrial Accident Commission, who gave the following opinion: "The present disability in my opinion is Dermatophytosis of the feet and toenails with an Ide sensitization eruption of the hands, forearms and lower legs. This condition may be aggravated by exposure to various types of materials used in applicant's work. This is not a case of Neurodermatitis per se but a state of allergic hypersensitivity, possibly induced by allergy to occupational materials." The patient has been treated by two competent dermatologists, who agree that her condition is primarily a contact occupational dermatitis but that now psychogenic factors are at play. Her therapy has consisted of x-rays, treatments and administration of cortisone, calcium, and antihistamines as well as locally applied medicaments. My problem is to determine compensability of the claim and to clear up the condition if possible.*

S. Howard Zoll, M.D., Long Beach, Calif.

Answer.—Fiberglas as such is as inert chemically as any other glass. A patch test, if suitably applied, would not be expected to give a positive result. There is one exception. For special purposes some Fiberglas is lubricated or otherwise coated or bonded with substances such as phenol-formaldehyde synthetic resins. Such ancillary treatments might be the source of positive responses. For precise diagnosis, it might be desirable to cleanse fully the fiber material and reapply the patch tests. A negative response should lead to exploration for coatings or other ancillary materials, and further tests should be applied using those materials in suitable dilution. Sensitization to phenol-formaldehyde on an allergic basis could account for the widespread distribution. Fiberglas may cause localized dermatitis on a mechanical basis. The condition simulates the well-known mechanical dermatitis of barbers from human hair spicules or its equivalent among brush makers from natural or synthetic fibers. This damage chiefly is limited to specific finger areas. Minute burrowing cysts may be formed. Secondary pyogenic or fungal invasion may arise. Any general distribution or systemic involvement apart from psychogenic influences is unknown.

A NEBULIZED SPRAY

To the Editor:—*What are the therapeutic values of a nebulized spray containing 2% camphor, 2% menthol, and enough liquid petrolatum to make 100%? It has been used as a nasopharyngeal spray in a machine that produces about 4 lb. (1.8 kg.) of pressure. The spray is applied while the patient inhales, an average of four inhalations being taken per treatment. The atomizer is a DeVilbiss 180, which may determine the particle size. Will the nebulized particles reach the alveoli and bronchioles under the above conditions?*

M.D., Ohio.

Answer.—A nebulized spray containing the ingredients listed is of doubtful therapeutic value. Liquid petrolatum preparations have been implicated in the production of lipid pneumonia. Nebulization may cause acute edema, desquamative alveolitis, and focal lipid pneumonia.

PARESTHESIA

To the Editor:—*Has paresthesia on the left side of the body been reported after use of antibiotics, secobarbital (Seconal), and/or cortisone for virus infection? The heart and arteries of the patient in question appear normal for his age. Results of neurological examination are otherwise normal. Roentgenograms of the head and body are normal, the blood pressure is 130/70, and the urine and blood are normal. The lymph nodes appear normal and the prostate is not enlarged. What treatment should be given?* *M.D., Mexico.*

Answer.—Peripheral neuritis has been observed following prolonged treatment with so-called broad spectrum antibiotics and has been attributed, without proof, to vitamin deficiencies. Paresthesias of the hands, tongue, and circumoral areas have been observed with streptomycin administration but have been especially prominent, even during the early course of therapy, with polymyxin. Toxic encephalopathy has been reported following use of streptomycin, and toxic psychoses have been noted with use of the sulfonamides and, rarely, penicillin or other antimicrobial agents. Paresthesias, marked numbness, and tingling have been described as one of the fairly common manifestations of chronic poisoning with the barbiturates. Transient paresthesias have also been observed to appear during the administration of large doses of cortisone. Thus, all three of the agents given to this patient may have been responsible for the symptoms described. The description of this patient suggests the presence of polyneuritis, but the strict limitation of the condition to one side of the body, with complete involvement of that side, raises considerable doubt as to the possibility of polyneuritis. Although it is stated that the patient's blood pressure and vessels were normal, his age is not given. It is possible that the unilateral subjective symptoms might have resulted from a concurrent but causally unrelated cerebral occlusion, due either to unrecognized vascular disease or to spontaneous cerebral vein thrombosis. It is well known that in persons with mild viral infections spontaneous thrombosis of cerebral veins may develop, which may vary in extent from a single vessel to diffuse closure. There is no treatment for this condition; if mild, it usually resolves itself without sequelae in two weeks or less; if severe, permanent neurological sequelae may result.

PHOTOENGRAVING FINISHER

To the Editor:—*What are the health hazards for a man whose life-long career is that of photoengraving finisher for magazines and newspapers?*

Robert C. Steinman, M.D., Stelton, N. J.

Answer.—No two shops are certain to carry out identical work operations. Likewise, in no two shops is the work of the finisher the same. In theory, the finisher's work is largely mechanical, employing burrs on the mounted etching to eliminate imperfections. In practice, the finisher may duplicate all steps of the engraver back to the point of the first work on metal plates. This being true, the potential exposures of the finisher are the same as those for the engraver. Some of these exposures are as follows: Chromium salts, chiefly ammonium bichromate, provide a threat of dermatitis and the remote possibility of lung cancer. Even more remote is the possibility of damage from ultraviolet rays and ozone from powerful carbon arc lamps. Ammonium hydroxide is always used. Powdered natural resins could cause sensitization leading to asthma or dermatitis. Varnish coatings may be applied to protect the underside of the plate; varnish constituents are substantially harmless, but the possibility of dermatitis exists. Concentrated nitric acid is the etching agent, its use involves some risks. In many shops benzene is still in use and, when used without protection, introduces the hazard of systemic benzene poisoning. The work of burring involves the risk of eye injuries, but only on a mechanical basis. Lastly, the black and colored printing inks could prove harmful, since the finisher always makes proofs to test the acceptability of his finished plates.

PERSISTENT URTICARIA

To THE EDITOR:—*Nine weeks ago, a patient was hospitalized with giant urticaria and angioneurotic edema due to camphorated opium tincture (paregoric). The acute stage subsided in six days with antihistamines and epinephrine. Two attempts to eliminate the antihistamines have caused a moderately acute flare-up. Scratch tests, declared negative, some of which showed a delayed skin reaction, were followed by another moderately acute attack. Is it advisable to continue with scratch or intradermal tests while the hives are present? Present treatment consists of administration of antihistamines, ephedrine, and calcium gluconate. Is any additional treatment indicated? Is such a prolonged attack unusual? Three previous attacks occurred, the first 12 years ago from unknown cause, the second four years ago caused by penicillin, and the third two years ago attributed to postoperative opiate therapy.*

M.D., Massachusetts.

ANSWER.—Products of opium will produce whealing on the skin in all persons whether they have allergy or not. Thus, while dermatoses and other allergy can occur from such drugs, the diagnosis must be made by means other than skin testing. Urticaria due to such drugs is almost always of short duration, and it is not likely that the persistence of the urticaria in the case described is due to the initial camphorated opium tincture reaction. On the other hand, persistent urticaria and angioneurotic edema from penicillin and less definite causes are common. While it is unlikely that the scratch tests were responsible for an acute flare-up, the further use of skin tests is likely to be of little value, since patients with urticaria and angioneurotic edema seldom show positive skin reaction to foods, even in cases in which the causative food allergen is definitely known. In order of importance, the following possible causes should be considered: (1) continued use of drugs, such as acetylsalicylic acid, acetophenetidine, penicillin and other antibiotics, sulfonamides, phenolphthalein, and barbiturates; (2) foci of infection, such as apical tooth abscess or infected tonsils or gallbladder; (3) intestinal and other parasites; (4) thermal hypersensitivity; and (5) emotional and other nervous factors. In addition to the symptomatic remedies already used, corticotropin or cortisone should be considered if the condition is disabling. Nonspecific therapy, such as use of typhoid vaccine or other protein therapy, or small dose histamine therapy may be advisable.

SICKLE CELL ANEMIA IN PREGNANCY

To THE EDITOR:—*A 21-year-old Negro girl who has had sickle cell anemia for 10 years, with numerous arthralgic episodes and one attack apparently of mild subarachnoid hemorrhage, is now five months pregnant. While the arthralgia attacks have not been noted since conception, the hemoglobin level remains about 50% (7.7 gm. per 100 cc.), despite intensive iron therapy. What complications of pregnancy or delivery would be expected? Since the patient has a moderately contracted outlet, cesarean section may be necessary. What are the dangers of surgery in this patient?*

M.D., Delaware.

ANSWER.—Sickle cell anemia is a serious complication in pregnancy, increasing the maternal and fetal hazard appreciably. The severe anemia may result in cardiomegaly and congestive heart failure. The patient should be under constant medical supervision. This anemia is not influenced materially by iron therapy, but additional iron may be desirable during pregnancy. The patient should be prepared for labor by bringing the hemoglobin level near normal by multiple transfusions. Delivery through the birth canal can be accomplished without increased risk, and cesarean section should be reserved for patients who have an indication for abdominal delivery. Regional anesthesia is desirable, and inhalation anesthesia should provide as high a concentration as possible of oxygen.

MICROGNATHIA

To THE EDITOR:—*A newborn child has a receded lower jaw. What is the cause, prognosis, and treatment of this condition?*

M.D., Rhode Island.

ANSWER.—This is a relatively rare congenital deformity consisting of an abnormally small mandible. It has been termed micrognathia or hypoplasia of the mandible. The mandibular ridge fails to contact the maxillary ridge, and, when the hypoplasia is marked, the tongue may be placed posteriorly, causing difficulty in breathing. When this latter difficulty arises, the infant may be placed on its face, or the tongue may be anchored in the anterior portion of the mouth in an attempt to make breathing easier. In severe cases a special type of splint may be necessary to pull the entire mandible forward. Permanent corrective procedures are best delayed until the craniofacial development is fairly well advanced (4 to 6 years of age). Among the operations that have been employed are the following ones: (1) addition of cartilage to build up the chin and a lower denture to fit in front of the natural teeth; (2) resection of the condyles and forward advancement of the mandible; and (3) lengthening the body of the mandible by horizontal sectioning (not usually recommended). When there is an associated cleft palate, its early closure is recommended. Since the jaws grow in three dimensions, there is a chance that if the deformity is not too severe it may improve considerably. Prognosis in any given case is difficult to determine.

HERPES ZOSTER AND TRAUMA

To THE EDITOR:—*A 66-year-old laborer was referred to this office as an industrial patient with inflammation of the right eye allegedly caused by foreign material. I found that he had bullae of the right frontal region, with swelling of the lids of the right eye, and I diagnosed his case as herpes zoster. The herpetic condition became severe but eventually cleared, leaving a pinkish mark on the right side of the forehead. The man was treated as a private patient. Since he was sent to me as an industrial patient, he felt that an injustice was done and obtained affidavits from fellow workers to the effect that, while drilling holes in rocks for blasting, compressed air threw "aggregate" into his face. The affidavits reached the hands of the superintendent. I told him that in my experience herpes zoster of the face, such as this man had, would not be of traumatic origin but that I would seek further information.*

Ralph W. Carr, M.D., Ketchikan, Alaska.

ANSWER.—Herpes zoster after trauma has been known to occur in cases in which the injury was severe enough to irritate the sensory root ganglion; however, Klauder (*J. A. M. A.* **134**:245 [May 17] 1947) has reported occurrence of herpes zoster after even light trauma, such as mild "bumps," superficial skin lacerations, and electrodesiccation of warts.

RENAL CIRCULATION DURING PERIODS OF REST

To THE EDITOR:—*In mild renal insufficiency, why do the kidneys function better when the patient is at rest or in a recumbent position?*

E. L. Carenee, M.D., Champaign, Ill.

ANSWER.—The renal blood flow is reduced, even in normal persons, during exercise and in upright posture. Glomerular filtration and tubular functions are less easily influenced, but they, too, will be affected by moderate to severe exercise. Furthermore, there is a diurnal rhythm in water and electrolyte excretion, with maximal function in the hours between 6 a. m. and noon and minimal function between midnight and 6 a. m. This rhythm is related to the sleeping and waking states during those hours. The glomerular filtration rate, while less involved, also tends to parallel the diurnal rhythm. In a patient with renal insufficiency, there would, therefore, be a favorable influence on renal blood flow and glomerular filtration rate during rest and in the recumbent position, especially since the redistribution of blood, even apart from an increase in cardiac output, is likely to benefit the renal circulation.

MALLORY-WEISS SYNDROME

To the Editor:—*What is the Mallory-Weiss syndrome as a cause or type of gastrointestinal bleeding?*

William B. DeMond, M.D., Denver.

Answer.—Like any provincial eponym, "Mallory-Weiss syndrome" should not be used without a reference or definition. It is a term well known in New England but apparently not elsewhere. In 1929, G. K. Mallory and Soma Weiss described 15 patients who, after long alcoholic debauches, had massive gastric hemorrhage. Four died, and autopsy revealed slit-like mucosal lacerations and acute ulcerations of both esophagus and stomach close to their junction. It was clear that these acute lesions had been responsible for the fatal hemorrhages. It was postulated that local trauma and acid reflux secondary to prolonged vomiting had been responsible. In a second communication three years later (*J. A. M. A.* 98:1353-1355 [April 16] 1932), six more cases were reported, and autopsy study in two that ended fatally confirmed the original conclusions. By common usage, Mallory-Weiss syndrome is understood to include hematemesis that may follow prolonged vomiting and consequent pericardial trauma in conditions other than acute alcoholism, such as acute food poisoning, uremia, and pernicious vomiting of pregnancy.

TORTICOLLIS DUE TO CERVICAL LYMPHADENITIS

To the Editor:—*I have seen many patients with unilateral torticollis secondary to acute sinusitis. The cervical nodes are enlarged and tender, and the sternocleidomastoid muscle, in spasm over the nodes, reveals tenderness, especially over its upper portion. Some patients turn their head to the affected side and others away from it. Can you explain this?*

M.D., Oregon.

Answer.—Torticollis due to painful cervical nodes is not a frequent complication of acute sinusitis. Usually the head is inclined to the affected side. When it is turned toward the healthy side, this may be explained as a compensatory effort of the opposing muscles to put the affected muscle at rest. This phenomenon has been observed in poliomyelitis, when the healthy opposing group of muscles contract to relieve the spasm of the affected group. This often leads to confusion as to which group is affected; however, the spasm of the unaffected group soon subsides. In the neck, torticollis due to spasm of a muscle overlying the affected glands will always occur on the same side if the primary infection is in the peritonsillar or pharyngomaxillary space, because of the cellulitis that affects the internal pterygoid and constrictor muscles. Torticollis due solely to inflamed cervical glands may be manifest on the healthy side because of the compensatory action of the opposing muscles.

TELESCOPIC LENSES TO IMPROVE VISION

To the Editor:—Time (60:87 [Dec. 15] 1952) *describes a telescopic lens developed by optometrist William Feinbloom of Columbia University. I have a patient with diabetes who has a severe retinopathy, who is interested in these lenses. Is this report in* Time *reliable?*

R. J. Askin, M.D., Pittsburgh.

Answer.—Telescopic lenses have long been used to improve vision not improvable by ordinary glasses. The magnification is about 2.2× for distance and up to 8× for close viewing. Contraction of the field is such that they are seldom of practical value and are useless when the macula is seriously involved. The type described by Feinbloom consists of 2+ lenses rather than the conventional Galilean type of a plus objective and a minus ocular. This provides a slightly smaller system and a negligible increase in the field of vision, but the magnification is about the same as in the familiar Zeiss and Kollmorgen lenses. A patient who would not be benefited by the older telescopic spectacles would almost certainly not be helped by the Feinbloom lenses.

PICA

To the Editor:—*A 2-year-old child persists in eating ordinary soil, and his parents have been unable to control this habit. What information is available on this tendency? Can some serious complication result?*

Don F. Russell, M.D., Van Wert, Ohio.

Answer.—Dirt eating in a child is the result of a perverted appetite, a condition known as pica. There is a natural tendency for this habit to cease spontaneously by the age of 3 or 4 years. Occasionally there is an underlying nutritional disturbance, such as anemia, or there may be a distinctly neurotic disposition. In some children pica seems to result from an unconscious urge to obtain minerals or vitamins that are absent from the diet. Occasionally, depending on the object swallowed, serious consequences may result from this practice, such as lead poisoning if the child picks lead-containing paint from toys or furniture; or various bezoars may accumulate in the stomach because of inability of the swallowed material to pass through the intestine, necessitating surgical removal.

ITCHY SCALP

To the Editor:—*A 61-year-old man has been growing balder for the last 15 years. His dry, itchy scalp is excoriated from scratching. He has used only 1% cyclomethycaine with no improvement. Is there any substance for topical treatment, except anesthetic creams, that he may use? He is in excellent health.*

M.D., Mississippi.

Answer.—The application of a cream or ointment containing 2% salicylic acid and 3% sulphur precipitate is usually effective in itchy scalp. Sometimes it is necessary to add to the mixture 0.5% of phenol or 3% of coal tar solution for an antipruritic effect. The standard textbooks on dermatology list numerous remedies for itchy scalp, and few, if any, recommend the procaine type of local anesthetic preparations, because of the relatively high incidence of dermatitis that results from their use.

CORTISONE DROPS FOLLOWING INTRAOCULAR SURGERY

To the Editor:—*What is the present practice regarding the use of cortisone drops following intraocular surgery? If this treatment is used, how soon after surgery is it started? How frequently is it used?*

M.D., Oklahoma.

Answer.—Several reports have indicated that cortisone retards healing of experimental corneal wounds as it does of wounds elsewhere. For this reason, cortisone is not generally used following intraocular surgery. The doses used in the experimental studies have greatly exceeded those that would presumably be used by the drop method in human beings. There is no evidence known to this consultant that cortisone drops have had any deleterious effect, although this treatment has been started immediately following intraocular surgery on numerous occasions. It is presumed to have some beneficial effect in cases in which tissue proliferation would be undesirable.

PREGNANCY TEST

To the Editor:—*Do you have any information on the relative accuracy of the Richardson pregnancy test (presence of estrone in urine) as compared to the standard rabbit test and on the accuracy of the same test on saliva to determine the sex of unborn babies?*

Sidney A. Cohen, M.D., Council Bluffs, Iowa.

Answer.—The accuracy of the Friedman (rabbit) test for pregnancy is greater than 95% when performed in a competent laboratory. The Richardson test is far less accurate than the several standard biological tests. Little data is available concerning the saliva test to determine the sex of unborn babies. Informal reports do not confirm the accuracy of this procedure.

PRECORDIAL NOISES HEARD AT A DISTANCE FROM THE CHEST

William Bennett Bean, M.D., Iowa City

In giving the Roger Morris Memorial address my topic should have some bearing on the medical philosophies and arts so notably embellished by Dr. Morris. I must add they have been abetted admirably by his successor, Dr. Blankenhorn. Stemming from the Oslerian tradition, which in turn was derived from continental and British sources, Roger Morris sought perfection in interpretation of signs and symptoms as revealed to the clinically sharpened senses. My discussion this evening will develop a theme in the area of physical signs where the humblest physician should be able to hold his own.

Medicine is at times fearfully serious and often gloomy, but the teaching and practice of medicine have their lighter moments and their amusing experiences, and we should make the most of them. Dealing with a topic in which physical diagnosis is the theme, it is appropriate that it fits in well with the extravagant American tendency to exaggerate; for here we have indeed the Paul Bunyan of physical signs, one which, defying the ordinary strait limits of the human frame, becomes at once a caricature and a giant. It magnifies itself in fact in the way we often tend to magnify by exaggeration after the fact.

My interest in precordial noises that can be heard with the unaided ear at a distance from the chest began in 1938, appropriately enough on Dr. Blankenhorn's service at the General Hospital, when I accidentally produced such a noise in a patient in congestive heart failure whose left lung was punctured during what had begun as an ordinary thoracentesis. When I visited him again several hours later, he had been alarmed by a noise "like a paddle wheel makes on the river," which he could hear and "feel." This simile and others likening the noise to "the grinding of gears," "the rustling of leaves," and "crunching up newspapers" are a pleasant tribute to the fertility of folk speechways. When the room was quiet, the sounds were barely audible at the foot of the bed. They could be heard clearly 2 ft. away. The sounds were synchronous with the cardiac systole. Left-sided pneumothorax was demonstrated by physical signs and roentgenograms, but no subcutaneous or mediastinal emphysema was found. The loud crackling noises (Hamman's sign) hurt the ears when the stethoscope was applied to the precordium. All abnormal sounds had disappeared in two days, and the patient made an uneventful recovery. Dr. Blankenhorn then told me of his considerable but unpublished experience with pericardial knock in World War I. This chance occurrence became "a burr that sticks in the memory," because of its close temporal association with two cases of interstitial emphysema of the lung that Johnson McGuire and I published soon after Hamman had aroused interest in the dramatic clinical features of the spontaneous form of this disorder. Another circumstance that gave my interest a wider sweep was a casual comment in Osler's essay on Sir Thomas Browne, in which he quoted from a letter about a "Woeman or mayd in Suffolk who had a julking and fluctuation in her chest . . . heard by the standers by," although this proved to be pyopneumothorax and a succussion splash.

Since these events focused my attention on noises heard at a distance from the chest, I have been on the lookout for other examples. This interest has been rewarded by the finding of several cases. Medical reports of these and other kinds of unusual and alarming noises heard at a distance have been found under the most diverse titles in the most obscure places. No cumulative index gives a clue to this sign, and, although my reading has been wide, surely many cases have been missed. Although I conceived the notion that I would review all published cases and produce an all-inclusive work, this was impossible without an "encyclopedantic" approach, time consuming beyond all reason. Most of the types of lesions and disordered functions that give rise to such sounds will be considered. While presentation of such miscellany may seem whimsical, it gives useful lessons in diagnosis, enabling the physician to give correct therapy, which may vary from reassuring the disturbed patient with mediastinal emphysema to aspirating air from the right ventricle of a heart churning with air embolism and thus saving a life.

From the Department of Medicine, College of Medicine of the State University of Iowa, and the University Hospitals.

Bibliographic references to medical reports quoted in this article and a more extensive consideration of the entire problem appears in Monographs in Medicine, Series I (Bean, W. B., editor, Baltimore, Williams & Wilkins Company, 1952, pp. 22-65).

This paper is the Roger Morris Memorial Lecture for 1953, delivered March 3, 1953, at the Cincinnati College of Medicine, Cincinnati. A portion of this lecture was given before the Midwestern Regional Meeting of the American College of Physicians, Chicago, Nov. 22, 1952.

DEFINITION

The term "precordial noises or sounds audible at a distance from the chest" is used to imply unusual loudness (rather than overacute hearing) and to indicate that the heart's action is responsible. This excludes wheezes and pleural friction sounds and even ribs cracking with a loud sound. The quantitative aspects defy analysis, since the subjective element in hearing has not been measured. Although the noises discussed here often come from outside the heart and usually are produced by impingement of the heart on air or air and fluid in abnormal places, they may be produced within the heart as extremely loud murmurs or by intracardiac air. Alteration of structure or abnormality of function of the lungs, pleura, mediastinum, pericardium, alimentary canal, and heart causes such noises under peculiar and sometimes poorly understood circumstances.

HISTORICAL BACKGROUND

Ancient medical records contain no reference to sounds heard at a distance from the chest. The Bible has no precordial companion for the abdominal rumblings of Isaiah "whose bowels sound like an harp." There is no thoracic counterpart of the borborygmal chorus of Aristophanes' "Clouds." In the posthumous works of Robert Hooke, written just 250 years ago, are these prophetic words: "Who knows but that one may discover the works performed in the several offices and shops of a man's body by the sounds they make, and thereby discover what instrument or engine is out of order!" Only with the perfection of the art and science of physical diagnosis was an interest in pulmonary and cardiac sounds and noises developed sufficiently to record cases of trouble in the engines and instruments of man's chest. Almost every kind of condition capable of producing such noises was identified during the resurgence of physical diagnosis in the 19th century, with contributions about evenly divided among French, British, and German clinicians. Experimentally many types of noises have been produced by a number of investigators, whose widely scattered work has not been gathered for review.

CHEST AND MEDIASTINUM

Pneumothorax.—Sounds heard at a distance from the chest have been described in left-sided pneumothorax, the spontaneous, therapeutic, and traumatic varieties. An open chest wound increases the likelihood of such noises occurring after injury. This sign is well known among clinicians familiar with therapeutic pneumothorax for tuberculosis. Indeed the act of inducing pneumothorax on the left side may cause unusual noises that are heard by the patient, attendants, and physicians. A division of cases has been made on the basis of the source of air in the thoracic cavity:

Traumatic Pneumothorax: It is by no means clear that some cases discussed under hydropneumothorax, notably those of Bricheteau in 1844, are not actually cases of traumatic pneumothorax or pneumomediastinum rather than pneumopericardium, which he diagnosed. Furthermore, it is likely that some of the German cases of frightening *Mühlengeraüsch*, which are attributed to air embolism, belong in the category of traumatic pneumothorax or mediastinal emphysema. Morel-Lavallée, in 1864, reported the case of a 27-year-old coach driver who was run over by a carriage. His chest was bruised and several ribs were broken. Subcutaneous emphysema was noted. The *bruit de moulin* was heard everywhere near the bed. This noise of the mill is a happy simile, since the combination of water splashing rhythmically and a background sound of wooden machinery and running water is elegantly reproduced in miniature by the sound of pneumopericardium or pericardial knock, as anyone knows who has listened to both. The sound lasted for five days and was so troublesome at night that the man could scarcely sleep. In due course the cure was complete. Although Morel-Lavallée thought the cause of the trouble was perforation of the pericardium, traumatic pneumothorax or mediastinal emphysema seems more probable.

The havoc of World War I was not without its small and casual by-product of clinical observations on the sound that was given the prosaic but accurate title of pericardial knock. The note of Captains Rees and Hughes in the *Lancet,* January, 1918, classic in its brevity and clarity, deserves quotation in full:

> We should like to call attention to loud "tapping" sounds which we have heard over the cardiac area in nine cases of wounds penetrating the left chest, where the missile had lodged near the heart, or where the track of the missile has passed in its close proximity. These sounds were quite distinctive and similar in each case, only varying in intensity. They were most marked when the patient was first examined after wounding and persisted for a variable time, occasionally for only 24 hours, but in one patient they were still present on evacuation a fortnight later. The sound continued even when the breath was held, although the intensity varied with respiration, increasing during inspiration and diminishing during expiration in all cases. It was sychronous with the heart beats, and when loud rendered the heart sounds inaudible. In four patients the sound could be heard with the ear held some inches away from the chest, and the patients were even conscious of it. The sound had no resemblance to pericardial friction, and in the cases referred to there was no suspicion of any gas being present in the pericardium, which has been described as giving rise to very extraordinary noises.

Henley Munden, bringing up the chance of sport and the risks of rabbiting, reported the following case:

> I was called to see a boy who had been accidentally shot in the head and left side of the chest when rabbiting. About an hour before he died a loud cardiac "click" developed which was synchronous with the heart systole and could be heard distinctly six or eight feet away. It bore no relation to the respiratory movements, as the respiration was Cheyne-Stokes in character and the sound persisted during the period of apnoea. The . . . click in the ear-piece of a telephone when the lever is raised illustrates it very well. During the last fifteen minutes of life the heart became very feeble and irregular and the "click" disappeared. I was very interested to read [an] explanation of the phenomenon, as I was quite unable to account for it. A postmortem examination was not ordered by the coroner, so no further investigation could be made.

Spontaneous and Induced Pneumothorax: I cannot find with certainty the earliest recorded case of sounds produced by pneumothorax. Perhaps the first is that of Cornils in 1885, who reported loud noises produced by the heart in a 23-year-old man with pulmonary tuberculosis and left pneumothorax. They were heard several times by persons some distance from the patient. Autopsy revealed left-sided pneumothorax and advanced tuberculosis. There is little doubt that previous experience with

Mühlengeräusch, the mill wheel noise of an earlier day, and its production by air embolism misled some German physicians into supposing that pneumothorax somehow caused air embolism and thus produced the loud and distantly heard sounds. I found another case published by Wolferth and Wood, in 1930, under the unlikely title of angina pectoris. In discussing the problem of pain in the chest they described a young University of Pennsylvania student who, in the throes of preparing for examinations, experienced pain over the heart. It was paroxysmal and became worse on exercise. It was supposed that a wrestling bout a week before might have precipitated the small pneumothorax on the left side found on roentgenograms. On running he had noticed "a sensation as though his heart were 'flopping around loose' inside of him," and "five days before, his roommate, while across the room, had heard his heart beating." The heart sounds, clear in the erect position, were not heard when he assumed the recumbent position.

Scadding and Wood recorded a number of cases in 1939. The first was that of a 26-year-old man who had a twinge behind the left shoulder blade. "Four days later, on first waking in the morning, he noted a 'curious bumping sensation' in the chest, accompanied by a faint sound." This was verified by the authors, who found a slight pneumothorax on the left side by roentgenographic examination. The sounds were heard only in the recumbent position. The second patient, a lad of 17 years, "complained of a heart beat on adopting a 'hunched up' posture; the noise could be heard by his mother a yard away." The sound could be heard off and on for 20 days. Roentgenograms showed the suspected partial left pneumothorax. The third case was that of a 19-year-old girl who had therapeutic pneumothorax on the left side for pulmonary tuberculosis. During induction, after 25 cc. of air had been injected, "a distinct click late in systole became audible in the region of the apex beat." It vanished when 150 cc. more were injected. On the next day, however, she had occasionally noted a clicking sensation in the precordium. Their last case, a retrospective and presumably autobiographical one, was that of a young man in perfect health who had "a sharp pain in the chest, and this was followed by an extremely loud peculiar noise accompanying the heart beat. The noise was so loud that it could be heard in the room below." Three weeks later it disappeared without complication, despite the diagnosis of rupture of a heart valve. This case, even allowing for the recollection of 20 years, holds the all-time record for loudness, as far as I have been able to ascertain. Frost and Bing described a 17-year-old youth in whom spontaneous pneumothorax developed on the left while bicycling. There was pain and breathlessness. "When the patient was placed on his left side there was a distinct extra sound which was now and again so loud that it was audible to the patient and even to other persons one meter away from him. The sound most resembled the clicking of the tongue used to urge on a horse."

Interstitial Emphysema of Lung and Mediastinum.—It is appropriate that Laennec, whose invention of the stethoscope opened the modern era of clinical observation of diseases of the chest, was the first to describe sounds heard at a distance in interstitial emphysema of the lung. Indeed he gave one of the earliest satisfactory descriptions of the lesion itself, noting "beads of bubbles along the pulmonary strands." He remarked that childbirth, weight lifting, and straining at stool were likely causes. In addition to the dry crepitant rhonchus with large bubbles, he observed subcutaneous emphysema. He said, "The patients are sometimes sensible of a kind of crackling in the part affected." This statement is the earliest record of sounds audible at a distance. Although Skoda confirmed these observations and Müller emphasized them, neither described sounds heard at a distance. There are undoubtedly other early cases on record, but the contemporary scene with its numerous papers had its curtain raising in Hamman's rediscovery of the clinical characteristics of interstitial emphysema of the lung. He gave the first description of apparently spontaneous episodes and so vivid a discussion of the subject that it at once caught the fancy of physicians. I should mention my good fortune in having seen one of his patients when an intern at Johns Hopkins Hospital. Excerpts from his papers include the following cases in which noises were heard at a distance from the chest:

> A 51-year-old physician had pain in the chest while shaving. On the evening of the next day while "lying upon his left side, he heard a curious loud, bubbling sound with each contraction of the heart. His wife sitting upon the bed beside him could hear it very plainly."
>
> A young physician, aged 25, had a sudden pain in the left side of the chest and a peculiar crackling sensation in the region of the heart. A few hours later "as he was leaning upon his desk he suddenly heard a curious crackling noise, apparently coming from that part of the chest where the pain was located. . . . It could be heard when the bare ear was held a foot from the chest wall."

It did not take long for reports of similar cases to be published. Morey and Sosman (1939) told of a husky medical student in whom a severe pain in the left upper precordial region suddenly developed while he was working in the laboratory. The pain radiated down his left arm and was different from pain associated with pneumothorax, which he had experienced previously. On the morning after the precordial pain began, he became conscious of a knocking and clicking in his chest. At times he could feel it, and at other times he could hear it. "Anyone standing directly in front of him could hear the noise." Somewhat later that year, McGuire and I reported two instances of spontaneous interstitial emphysema of the lung and described the patient already mentioned in the introduction. The first patient, a 17-year-old school girl, felt a pain in the chest while dribbling a basketball, went home, and went to bed. "Shortly afterwards she heard a curious noise in her chest and told her mother that she thought she had pleurisy." In the other patient, sounds were not heard at a distance.

Pinckney, in 1941, reported the remarkable case of a 24-year-old white woman who had six different attacks of spontaneous pneumothorax, in some of which there was interstitial emphysema. On her third attack she had dull pain and dyspnea. "She also noted a loud, clicking, snapping noise audible at all times no matter what position she assumed. In addition when lying on the left side she heard another sound, a crunching, crackling sound like small chicken bones being crushed. This sound she cannot say with certainty was synchronous with her heart beat. Both sounds were easily audible to persons in the room with her." On her fourth attack three months later, pain developed while she was walking. Several hours afterward there was a loud clicking noise, and a crunching sound became audible. Roentgenograms showed a small pneumothorax on the left side. With her fifth attack 15 months later, she had only a heavy sensation. "Again the very loud clicking noise, synchronous with each heart beat, was easily audible to anyone within twenty or more feet, and slightly less audible was the crunching noise when she sat leaning forward on her left side." This lasted for six weeks, during which time her lung reexpanded. Pinckney reported another case, that of a 24-year-old man in whom severe pain developed while at rest. While lying down at bedtime on the third night after the onset of the pain, both the patient and his wife were startled and terrified to hear a loud clicking noise emanating from the region of the patient's heart, audible several feet away. It lasted only 24 hours and gradually subsided. The presumptive diagnosis was mediastinal emphysema. Miller reported the case of a 27-year-old resident physician at the Cincinnati General Hospital who had a sudden knife-like pain in the chest while making ward rounds. He was put to bed. A small left-sided pneumothorax was discovered. Two days after the painful attack, he had recurrence of sharp pains over the left precordium. "Soon after this he heard peculiar loud clicking noises in his chest synchronous with the heart beat. Palpation by the patient over the sternum revealed a thrill was present. The patient's wife who was standing five or six feet away from the bed was also able to hear these sounds." Greene reported the case of a 41-year-old Negro physician who, while sitting at his desk, had severe substernal pain, which radiated to the left shoulder. He went to bed immediately and noted that lying on his left side produced more pain and caused tapping, crunching, and bubbling sounds to come from the chest. These sounds were audible to his wife at the bedside and were synchronous with the heart beat. Later a roentgenogram of the chest revealed air in the anterior mediastinum.

During the pandemic of influenza in the latter part of World War I, many observers reported interstitial emphysema of the lung and pneumothorax complicating influenza and its attendant pulmonary sequelae. Although subcutaneous emphysema and pneumothorax were recognized, apparently no one described Hamman's sign or noises heard at a distance from the chest. Mediastinal emphysema and pneumothorax complicating parturition has been recorded as a not too rare complication. In the review of Gordon in 1927 and that of MacRae in 1949, no mention is made of sounds heard at a distance from the chest, although the characteristic noises heard by auscultation were described in many instances.

Traumatic Mediastinal Emphysema.—It is not always clear from descriptions whether certain traumatic cases in which precordial noises were heard at a distance from the chest should be put in the category of mediastinal emphysema or pneumothorax or both. Steiger, in 1864, described a man who fell, fracturing his arms, shoulders, and ribs. He had marked precordial tympany, and a splashing, metallic sound synchronous with the heart beat was heard at a distance from the chest. Since this patient recovered it is not known whether he had pneumothorax, pneumomediastinum, or mediastinal emphysema, but in all probability his case represents the same type in which pericardial knock is heard. In 1875, Leonspacher described precordial tympany and musical heart sounds heard 3 ft. from the bed in a man who had fallen on his back. He, too, recovered, and the exact nature of the lesions was not known. Weil recorded an instance of mediastinal emphysema in a young man who was given an injection of procaine into the brachial plexus, in whom sounds were heard at a distance for a few minutes. Jehn in 1921 described an 18-year-old boy who fractured his larynx. Sounds synchronous with systole and diastole were heard at a distance from the chest. After death, air as well as pus was found in the mediastinum.

ALIMENTARY CANAL

Rupture of the Esophagus.—In 1722, Boerhaave reported the first case of rupture of the esophagus. "We have the surprising observation which is perhaps the only one published, namely the illustrious Baron Wassenaer, Lord High Admiral to the Republic, after intense straining and vomiting broke asunder the tube of the esophagus near the diaphragm so that after the most excruciating pains the aliments which he swallowed passed, together with the air, into the cavity of the thorax, and he expired in 24 hours." Unfortunately, there is no comment on any sounds heard at a distance from the chest. In a number of recent reviews that have emphasized the importance of diagnosing rupture of the esophagus because of the possibility of surgical relief of the condition, there is no comment on noises heard at a distance from the chest. As far as I have been able to find, the only clearly demonstrated case was that of Begbie, published in 1863, in which he described a patient with carcinoma of the esophagus which ruptured into the pericardium, and splashing and churning sounds were heard at a distance from the chest.

Ectopic Borborygmi. — Portions of the esophagus, stomach, and colon may contain trapped air, which produces sounds heard at a distance, with the heart beat providing the percussion force. At times the pulse can be counted from such sounds, although there are apt to be variations produced by respiration, changes in position, and belching or expulsion of flatus. A unique case of precordial noises reported in a brief note published by Allen is quoted in full:

> A woman came for examination complaining of "heart trouble" of unusual nature. She had been disturbed by a noise synchronous with the heart beat which had appeared intermittently for two years. It frequently bothered her during the day but was likely to be particularly troublesome when she was lying down at night. The sound was so loud that it was heard for a considerable distance from the body. Not only the patient but other people could hear it; the latter even before the patient entered the room. She described it as resembling the splashing of water in a mill. The cause of the noise was discovered more or less by accident. She had moderately severe anemia which had not responded to treatment. X-ray examination of the gastrointestinal tract was made in order to see if there was any lesion responsible for loss of blood. It was found that she had a diaphragmatic hernia; the large part of the stomach was lying in the chest. The sound was produced through action of the beating heart on the contents of the intrathoracic stomach.

Greene, who has contributed notably to the study of such noises, described some curious observations. In one patient with a pneumothorax on the left side who was being prepared for introduction of more air, a metallic, knocking sound began to emanate from the chest, audible at a distance of 3 ft. Several minutes later borborygmus was heard, and the sound disappeared without introduction of more air or changes in position. In this and another patient, introduction of air into the colon, sufficient to distend the splenic flexure again produced the noise with the metallic, knocking quality, sometimes heard in systole, sometimes in diastole. It was concluded that when heard in systole it was caused by rotation of the heart, which struck the diaphragm immediately above a bubble of gas in the colon, and that when heard in diastole it was caused by the free fling of the uncushioned heart striking the diaphragm.

HEART

Pneumopericardium.—Even before Laennec's observation, Morgagni spoke of having heard the splash of water and air in the pericardium, and Portal had encountered this combination at autopsy without recording clinical findings. The first real advance in this topic was the observation of Brichteau in 1844, who described a Polish veteran of Napoleon's army who was struck down by a blow on the chest with a carriage tongue. His wife heard "boiling" in his chest, and Brichteau and eight assistants all heard it. The man died, and autopsy disclosed pericarditis, with the profuse formation of evil-smelling gas. Stokes' (1855) observations speak for themselves:

> The patient was a young man of lymphatic temperament, who had laboured under an attack of acute pericarditis for a few days before I saw him. On my first examination he presented the usual signs of dry pericarditis, with a considerable effusion of lymph of the ordinary consistence. The rubbing sounds, though loud and distinct, had nothing unusual in their character, and the patient suffered but little distress. After two or three days I saw him again, and found that his state had become very much altered. His appearance was haggard and worn, and he complained of extreme exhaustion, which he attributed to a total deprivation of sleep. This was induced by the extraordinary loudness and singular character of the sounds proceeding from the cardiac region; for though up to this period the rubbing sounds were distinctly perceptible by means of the stethoscope, the patient was quite unconscious of their existence. They had suddenly, however, become so loud and singular, that the patient and his wife, who occupied the same apartment, were unable to obtain a moment's repose. On examination, a series of sounds was observable which I had never before met with. It is difficult or impossible to convey in words any idea of the extraordinary phenomena then presented. They were not the rasping sounds of indurated lymph, or the leather creak of Collin, nor those proceeding from pericarditis with valvular murmur, but a mixture of the various attrition murmurs with a large crepitating and gurgling sound, while to all these phenomena was added a distinct metallic character, and I could form no conclusion but that the pericardium contained air in addition to an effusion of serum and coagulable lymph.

The most detailed and clear-cut study of the problem was reported by Morel-Lavallée, in 1864. After some shrewd speculation, he reports several cases. The first was that of a 20-year-old carpenter, previously healthy, who fell from the seventh floor, hit a projection on the fourth, and crashed to the ground. Shock, fractured left leg, incomplete paraplegia, and hematuria ensued. On the next day the man said that during the night he had been awakened several times by a noise coming from the left side of the chest resembling that produced by blowing into a wide bottle. It lasted seven days and was never heard in a sitting position. He died suddenly while trying to sit up on his bed. Autopsy showed multiple ruptures of the pericardium, with air in it, slight pneumothorax, and communication between pericardium and pleura. Two kinds of noise were heard, one the mill wheel sound and one a kind of metallic tinkle. Another patient, a 45-year-old coachman, had fallen beneath a horse, which stepped on his chest. A bruise the size of the hand was found over the sternum. Bony crepitus was detected. After a stormy course, precordial sounds increased in intensity and were heard 1 m. from the chest. Autopsy revealed widespread sepsis, with traumatic pyopneumopericardium.

Walshe recorded the melancholy accident of a careless sword swallower, who pierced his pericardium through the gullet and had a noisy pneumopericardium with unadvertised sound effects. James, in 1904, made an extensive survey, which included most of the previously reported cases along with a case report of his own. In a 25-year-old Irish woman pneumopericardium developed as a sequel to injury of the esophagus from a fragment of mutton bone. The pertinent observations were as follows:

> When the patient takes a full breath and holds it there is heard by the listening ear, held twelve inches from the chest wall, a peculiar clicking sound synchronous with cardiac systole; this click has a musical quality with the quality of a succussion sound or splash. The first sound is accompanied by a loud metallic tinkle of splashing, gurgling quality, suggesting the sound made by an old-fashioned overshot waterwheel, the *bruit de la roue hydraulique.* It is as if a very marked succussion were brought out by each systolic contraction of the heart, together with many metallic tinkles. . . Its intensity varies from time to time without apparent reason.

Air Embolism.—It is not surprising that air embolism is a subject about which there is much rumor and general discussion and relatively few case reports, since air embolism indicates an accident. Durant, Long, and Oppenheimer discussed this problem in their article on pulmonary air embolism and stated, "In the pulmonary or venous form the presence of air in the right ventricle produces a loud churning sound often readily heard without stethoscopic aid which is known as the mill-wheel murmur. This murmur appears almost immediately after air has entered the venous circulation." In 1950, Stallworth, Martin, and Postlethwait described a patient in whom air embolism developed as a consequence of an operation or infusion of blood during deep shock, and the characteristic sound was described as a mill wheel murmur. Although it was not explicitly stated that this was audible at a distance from the chest, a letter from Dr. Stallworth mentions that, once it had been heard with the stethoscope, close attention permitted the observers to hear it without the stethoscope.

Heart Murmurs.—Before the introduction of the stethoscope focused the clinician's attention on sounds produced by the heart, there were references to audible precordial sounds found in conjunction with heart disease. Some of these are described so vaguely that they are of little value. Others probably merit inclusion in what has now become a formidable list of endocardial murmurs heard at a distance by the unaided ear. Allan Burns described a patient seen by Dr. Brown in the Edinburgh

Hospital, a man with dropsy who had "a jarring when the ventricles contracted; and when the hand was laid on the side it resembled the feeling of a varicose aneurysm; his expectoration when he used exercise was bloody; he had unusual palpitation, jarring sensation and hissing noise, as of several currents meeting; the sound was frequently audible as in the varicose aneurysm." Mitral stenosis, pericarditis, and induration of liver and lungs were found after death. Burns referred to the phenomenon as "audible palpitation," and the presumption is strong that the sound was heard at a distance, although it is not explicitly so stated.

Laennec had given this matter detailed study, and his observations are so unusual that they must be ascribed to marvelous acuity of hearing or to his having been carried away by rhetorical enthusiasm. The following quotation is from Forbes' translation:

> It had long been believed, but rather on the faith of traditional report than from actual observation, that the pulsations of the heart may be sometimes heard at a certain distance from the patient. Corvisart informs us that he had observed this fact but once, and only then on placing the ear very near the chest. Many years since, I was informed by several patients, that they were subject to palpitations of such severity that they could be heard at the distance of several paces; and one of these patients, as well as persons of credibility, witnesses of the fact, assured me that in his case the palpitations, could be heard in the chamber adjoining that in which he slept. I observed this phenomenon for the first time in the year 1823, in the case of a young woman; and having since then paid particular attention to the circumstance, I am convinced that although it is very uncommon to meet with it in so great a degree as that just mentioned, it is very common to find it in a less degree, such, namely, as to be heard at a distance of from two to ten inches from the chest. Several of my colleagues, to whom I had mentioned the fact, have likewise noticed it several times since; and M. Lerminier, among others, was kind enough to send to my Clinic, in 1824, two patients in whom it was perceptible in a very considerable degree. In no case have I myself heard the pulsation at a greater distance than a foot and a half or two feet; but we can readily admit the possibility of this. I have several times ascertained from the perfect accordance of the sound with the pulse, that it was owing to the contraction of the ventricles. I do not recollect to have ever heard it produced by the auricles. Out of more than twenty subjects in whom I have heard the pulsation at a distance of from two inches to two feet, three or four, at most, were affected with organic disease of the heart. All the rest labored under palpitation of a purely nervous kind. . . . Never having had an opportunity of examining the body of anyone who had presented this phenomenon, I cannot speak with any certainty as to the organic cause of it; but I am induced to consider it as owing to the presence of a greater or less quantity of air in the pericardium.

Such a distantly heard sound appeared in Laennec on his deathbed. Andral's commentary on this interpretation is worth including: "Laennec's explanations of these sounds of the heart heard at a distance, appears not to be sustained by fact. It is a mere supposition of his that gases in the cavities of the heart produce this phenomenon. The supposed analogical facts cited by him in support of his opinion, have no real analogy."

In the classical description of hyperthyroidism which has given him eponymic fame, Graves encountered the phenomenon of heart sounds heard at a distance: "In one the beating of the heart could be heard during the paroxysm at some distance from the bed, a phenomenon I had never before witnessed, and which strongly excited my attention and curiosity. [The patient], her friends, and Dr. Harvey all testified the frequency of this occurrence, and said that the sound was at times much louder than when I examined the patient, and yet I could distinctly hear the heart beating when my ear was distant at least four feet from her chest!"

Stokes reported two instances of murmurs heard at a distance in "extensive and irregular ossification of the aortic orifice." The sounds were audible to the patients, and in one "perception of these sounds was the principal cause of his suffering for his general health long continued excellent, and the heart's action was but little excited. This gentleman once observed to me that his entire body was one humming-top. The loudness of the tone varied with the force of the heart. When I first saw him the sounds were audible at a distance of at least three feet, but when the force of the heart had been reduced . . . the loudness of the sound at the aortic orifice was so much reduced as to render it inaudible, unless by applying the ear." Humming was heard over the limbs, probably transmitted by bone.

Simpson described a 40-year-old man who, while helping to move a piano down a flight of stairs, "suddenly felt something give way in his chest, and immediately heard a noise proceeding from it, which he compared to that 'made by a young frog.' " It was audible to those about him as well as to him. It could be heard for nine months and then faded out. Four and a half years later he died of heart failure, having signs of free aortic regurgitation. The diagnosis of rupture of an aortic valve was made.

Frew and Finlayson related the distressing sequel to a brawl that befell a 39-year-old man. Although no blow was struck, there was much straining and struggling. There was a " 'cooing sound' in his chest resembling the soft cooing of doves. . . . This cooing sound was also heard so plainly by his wife that she complained of its disturbing her while in bed with him." It was heard readily 1 to 2 ft. away from the chest; and there were signs of aortic regurgitation. The sound could be heard for many months but was gone 19 months after the onset. He died in congestive failure 34 months after the accident.

In his classic study of rupture of the aortic valve, C. P. Howard described 21 cases in which the murmur was heard by the patient and his friends. This number represented about a third of the nontraumatic cases. The variations in loudness of the sound are illustrated by the following reports: Quain's case, heard several inches from the chest; O'Neill, 6 ft.; Dupuis, 15 to 20 cm.; Tranquilli, 50 cm.; Schneider, 25 cm.; and Schlecht, several centimeters. Along with other examples, the murmur was compared to the "croaking of a frog" and the "cooing of a dove or pigeon" and was described as a "rumbling, rustling noise," a "humming noise," a "whistling noise," a "buzzing in the chest," a "musical murmur or thrill," a "whining noise," and even a "rattle in the head."

Bellet and his associates have made a notable contribution in the problem of precordial noises in their articles on musical murmurs of aortic insufficiency. They emphasized the part played by eversion of an aortic cusp diseased by syphilis. In their first paper, only 1 of 11 patients had murmurs heard at a distance: "The patient's bedfellow was considerably annoyed by the unusual and constant noise." In this and three other instances the murmurs were audible to the patient, presumably in the same distressing way as to Stokes' poor patient, who likened himself to a humming top. This distinction between murmurs heard by a patient but not by others suggests that vibrations may be transmitted directly to the cochlear apparatus through the bone, blood vessels, or other tissues of the body rather than by air transmission. In their second group of patients, 4 of 18 patients complained of hearing noises that interfered with sleep and made them nervous. One man produced such a noise that it disturbed his wife at a distance of 7 ft.

While this section was being written, I saw a patient with rupture of the aortic valve on the Medical Service of the University Hospitals at Iowa City. He was a 41-year-old cement worker. He and several members of his immediate family had dislocated lenses but no other stigma of arachnodactyly. Though he had had infrequent bouts of shortness of breath with exercise and other spells of palpitation with tachycardia, they had not interfered with work. He had no history of rheumatic fever. When he was examined for the Army in 1941 nothing was found wrong with the heart, but he was disqualified because of his eyes. On Sept. 19, eight weeks before hospitalization, he experienced the sudden start of dyspnea while he was laying a cement floor, but there was no direct connection with any act of lifting or straining, even though he joked about handling 100 lb. objects as trivial. Dyspnea even at rest has characterized his state ever since. Orthopnea and edema increased in severity until he was admitted to the hospital. Examination disclosed the usual features of congestive failure and the peripheral and cardiac signs of free aortic regurgitation. After a regimen of rest, digitalis, diuretics, and restriction of salt, he was much improved. The heart evidenced great overactivity, chiefly of the left ventricle. A diastolic thrill was intense in the second right interspace and the third and fourth left interspaces. Pulsation of the subclavian and carotid arteries gave evidence of the wide pulse pressure, which was measured as 150/0 mm. Hg. There were pistol shot sounds, Duroziez's murmurs, a Corrigan pulse, and capillary pulsations. At the base there was a loud diastolic murmur with a rough grating quality, not at all musical. This spread over the entire precordium, and over the mitral area I heard the presystolic rumble of a Flint murmur, which had been mistaken for that of mitral stenosis on admission. A loud systolic murmur occurred at the base. There was no aortic valve closure sound, but the pulmonary second sound was loud. The diastolic murmur was so loud that it was clearly heard by the unaided ear 1 in. from the chest on the ward and 6 in. away in a quiet room. It was not audible to the patient. Roentgenograms revealed 4+ left ventricular enlargement and no left auricular enlargement. Electrocardiograms showed the pattern of left ventricular hypertrophy. After further convalescence the patient was discharged, and although his exercise tolerance is poor, he is not in congestive heart failure.[1]

BIZARRE AND MISCELLANEOUS SOUNDS

Some records of sounds heard at a distance from the chest are so obscure as to defy precise classification. Perhaps the first example of such strange cases is the one in a footnote in Laennec's book on auscultation, a case recorded by Andral, as follows: "I lately saw a woman who complained of palpitations of the heart. Each stroke of this organ was accompanied by a peculiar gurgling sound, which evidently came from the precordial region, and was heard only when the heart struck the ribs; it was perceptible at a distance." Frost and Bing, whose admirable but brief review of the subject of loud precordial noises appeared in 1940, described a healthy 22-year-old woman who was seized suddenly by a "crick in the back," a sensation that something had come loose in her chest, and then pain in the chest and left shoulder. A blowing systolic murmur and some vague scratching sounds were heard along the left sternal border. During hospitalization, she had a sense of precordial fulness, "like a ball being squeezed out between two fingers," and sounds came from her precordium so loud that they were heard 3 m. away. The sounds were synchronous with the heart beat and were loudest when she was lying on her left side, disappearing when she turned to the right. Phonocardiograms showed the sounds to be systolic in time but spaced at variable intervals from beat to beat. Intensive roentgenographic and other studies failed to reveal any lesion of the lung, pleura, pericardium, or heart. The likeliest guess is that pulmonary interstitial emphysema was responsible, but the issue is in doubt.

Warburg, who scarcely mentioned such phenomena in his monograph on cardiac trauma, described elsewhere a man with mitral stenosis and auricular fibrillation observed many times in congestive heart failure. With an obscure infection he had fever of short duration, and "during the last 24 hours he had heard a sound from his chest which he described as though something were dripping; he said that he thought his heart had burst. His wife was able to hear the sound when she was lying in the bed beside him. I was able to verify his statements. At every heart beat a clicking or slightly sonorous sound was audible in the room.... A phonocardiogram showed that besides the sounds usually found in this patient there was a new murmur, partly during the systole, partly immediately after the systole. It was quite clear that the new sound included higher frequencies than the other sounds."

Levine and Harvey recorded the case of a 45-year-old woman with well-compensated mitral stenosis and auricular fibrillation. After exercise, a weird sounding, rough musical murmur "was actually heard with the naked ear a foot away from the chest . . . For several years she had been aware of a peculiar noise in her chest at times. We have heard it at irregular intervals, sometimes only for a few seconds, at other times constantly and then it might be absent for days. It is not related to position of the body or to breathing. . . . There is no x-ray evidence of diaphragmatic hernia or any other abnormality that might throw light on its causation."

Dr. Lewis January has called to my attention a rare instance of a healthy young man whose heart sounds were clearly audible several inches from his mouth when it was held open. He had no heart disease. X-ray study of the chest, esophagus, and upper gastrointestinal tract showed them to be normal. Perhaps some anatomic quirk permitted his esophagus to be patulous when his mouth was open and to act as a megaphone. Although I have looked for such a sign many times, I have not yet come across it.

---

[1] Since submission of this paper for publication this man died suddenly at home. No autopsy was performed.

In conclusion, I offer an autobiographical note: Occasionally, when my stomach contains just the proper quantity of fluid and air, a happy postprandial mixture, and when semirecumbent in an easy chair, a systolic tinkle or splash is clearly audible to me and very diverting. It has been heard by others a foot away. The cardiac impulse on the diaphragm and stomach obviously produces the sound. It generally vanishes after a few minutes or can be eliminated by belching; but swallowing air or air and water has not brought it back at will.

COMMENT

Beyond serving as a repository for esoterica, is there usefulness in collecting such diverse disorders with the common denominator of noise heard at a distance from the chest? Certain gleanings may reward closer study. While the figures defy statistical analysis, data in the table suggest that loud heart murmurs are the commonest cause of the phenomenon, followed by interstitial emphysema, pneumothorax, and pneumopericardium. Records of the other conditions are less numerous. From the topographical and mechanical view, air free in the chest from interstitial emphysema or pneumothorax, spontaneous or accidental, heads the list; cardiac murmurs come next and then pneumopericardium. Since the sources of this review have been casual and the survey sporadic, the data may not be representative. In some specialties, particular problems may be missing or too heavily represented. A surgeon's reading and experience would no doubt assemble a different array of noise producing conditions.

Conditions Causing Precordial Noises

The general problem of such noises may be considered by using interstitial emphysema of the lung as an example: In such a disturbance the noises heard at a distance are an exaggeration of a sign that much oftener is confined to the chest and can be heard only by the customary method with the stethoscope. Noises heard at a distance may be so loud as to command instant notice or may be heard by the unaided ear only after being heard with the stethoscope and then listened for attentively. Phonocardiographic records, of which several are reported, serve to demonstrate the sometimes irregular timing of such noises during systole and perhaps quiet the suspicion of skeptics that such noises are illusions. What constitutes the urge to publish case reports has never been known, but one has only to hear these eerie sounds to appreciate the high clinical drama. Published cases represent an unknown fraction of those met clinically. Certainly, illuminating papers, such as the late Louis Hamman produced, were followed by a wave of case reports, and a useful diagnostic sign caught popular fancy and became a medical fashion.

Clinical features of spontaneous interstitial emphysema of the lung may suggest acute myocardial infarction, but usually the complaint of pain in the chest is more insistent than the meager signs of difficulty. The patient is in pain but looks well, usually breathes easily, and is not in shock. Generally he is young, vigorous, and active, without signs or a history of hypertension, angina, or vascular disease. Later reactions, such as fever, leukocytosis, and rapid erythrocyte sedimentation, do not follow. Such a loud noise may be produced only in certain positions, so that change of position or movement will enhance or quiet the ticking chest. The noises have been reported as audible at a distance in about 10% of the recorded cases. The loudest noise, measured in distance heard, was perceived 20 ft. from the patient. Duration varied from two hours to two weeks. There was much variation in the intensity; sometimes everything would be quiet and then the sounds would return. As a general rule, they would come and go. In all except one case, the sounds were heard best with the patient lying on his or her left side, and many were able to demonstrate the sound at will by assuming the proper position. I saw one young man whose main distress was not the pain in the chest but the fact that the noise coming from his chest was so loud his wife made him sleep in the next room. He could not turn and eliminate it, but finally it went away, and he gained his reprieve. Several other reports suggest that such noises are a rare cause of temporary domestic infelicity, and they are alarming to patient and family. Indeed, fear and curiosity occasionally have brought the patient to the doctor, since there may be little associated pain.

Subcutaneous emphysema has been recorded in only a few cases, but since it may be confined to a small area and be ephemeral it is easily overlooked. In almost all cases of interstitial emphysema of the lung, if complicating pneumothorax occurred it occurred on the left side. Often it has been so small that only careful search with proper alignment has produced diagnostic roentgenographic shadows. Right-sided pneumothorax does not appear to be rarer than the left-sided kind, but only rarely has it been found in association with the crunching, bubbling, paper-rustling sound (Hamman's sign) so characteristic of mediastinal emphysema. I found no record of right pneumothorax associated with the distantly heard noise. The most comprehensive discussion of such sounds in interstitial emphysema was given by Greene, who differentiated between two classes of sounds. "The bubbling, crunching, clicking and some of the tapping sounds are due to the heart rubbing against emphysematous blebs in interstitial emphysema of the lung and mediastinum. The knocking and tapping metallic sounds, on the other hand, are due to the heart striking an emphysematous bleb on the median aspect of a partly collapsed left lung or the diaphragm immediately over a gas bubble in the splenic flexure of the colon in the presence of pneumothorax of the left side." The evidence on which these conclusions are based is the fruit of careful study, and, short of detailed human experiments, is the best we are likely to get from observing the effects of accidents and disease.

While the absence of distantly heard noises can only be inferred, the consistency of the record suggests that there is clinical significance in its omission from certain reported cases; for example, in the extensive literature on pneumoperitoneum, such noises are not listed. I have not encountered the phenomenon in reading about or seeing the abdominal catastrophes in which air leaks from the ruptured gut. It is not recorded in reports of interstitial emphysema and left-sided pneumothorax in infants and young children, although Hamman's sign occurs. The assumption is that the noises require the larger heart and fuller sounding board of the adult thorax for their distant propagation. Likewise, the left ventricle and aortic valve rather than the less muscular right ventricle have been associated with heart murmurs heard at a distance.

Diagnosis of such rare conditions is important, because the cause may be a mechanical crisis that can be corrected or eased. Delay or confusion may be fatal. On the other hand, if the causal condition is innocuous, it is well to avoid mistaking it for conditions of ominous import. In order of urgency, the *Mühlengeraüsch* or mill wheel sound of air embolism stands first. Its clinical debut, always unexpected, is associated with an opening by wound, scalpel, or needle by which air gets into veins. Immediate rotation to the left lateral position or the Trendelenburg position, trapping air bubbles above the blood in the right ventricle where they may be aspirated with a needle and syringe, may be lifesaving. Inhalation of 100% oxygen may help.

Rupture of the esophagus, which I have seen produce Hamman's sign, probably can cause loud noises, even without pneumopericardium. Since surgical cure in such a calamity may now be anticipated, the diagnosis of a ruptured gullet should be considered, especially in cases in which a history of extreme vomiting or instrumentation makes the condition probable.

Traumatic pneumothorax, pneumopericardium, and pneumomediastinum with the connotation of crushed ribs or penetration by a missile or foreign body, obviously urgently require treatment. The attending noise may indicate the extent of damage, which otherwise is not apparent. Treatment is that of the underlying condition.

Spontaneous interstitial emphysema of the lung implies pneumothorax and, at times, the hazard of tuberculosis. The noise heard at a distance has not been nearly so ominous as it has seemed to the victim, always amazed and often terrified by such uncanny behavior. Thus, diagnosis usually permits reassurance, since in all recorded cases the patients have survived. It should be kept in mind that tension pneumothorax may lurk under this clinical camouflage. Also, "air lock," the dissection of air through the lung or hilum under enough pressure to impede blood flow, may require more heroic measures, i. e., administration of 100% oxygen or, perhaps, surgical intervention to stop the leak if it can be found. In general, the major role of the physician in these cases is to calm terror by bringing assurance.

Noise from the alimentary canal may rarely lead to the discovery of hiatus hernia with an errant stomach or colon. Loud murmurs, when they have arisen out of the innocuous quiet of the past, especially under some stress or accident, may call to mind the likelihood of ruptured aortic valve or the turning inside out of a syphilitic valve cusp. Giving a better view of prognosis, such diagnostic tours de force escape the odium of academic banality, and who would say that the surgeons will not soon be able to repair or reline stenotic or ruptured valves? Pneumopericardium, apparently of great rarity now, calls for a review of the eroding and destroying processes that permit air to escape into the pericardium from adjoining air-containing structures. Therapeutic pneumopericardium has its own obvious cause, and its insubstantial vogue is past.

SUMMARY

A variety of clinical conditions that may be associated with precordial sounds heard by the unaided ear at a distance from the chest is assembled, compared, and assessed. The commonest causes of such sounds are cardiac murmurs produced by valve rupture or other lesion, often abrupt in onset and a consequence of stress or strain. Next in order of frequency come interstitial mediastinal and pulmonary emphysema, both spontaneous and traumatic. These are followed by spontaneous and traumatic pneumothorax, pneumopericardium, noises the heart produces by striking air-containing gut, air embolus, and a small mysterious miscellany of unexplained sounds. Since the noises considered have diverse sources there is no pathophysiological common denominator to compare with the clinical fact of abnormally great volume of sound. With such differences in cause and, hence, in necessary treatment and prognosis, attention should be directed to the cause, which usually comes to light on careful clinical scrutiny.

If the spirit of Robert Hooke were with us on this occasion, I am sure his interest in natural phenomena would have had some stimulus, and perhaps he would be amused at my answers to his query, "Who knows but that one may discover the works performed in the several offices and shops of a man's body by the sounds they make, and thereby discover what instrument or engine is out of order!" This commemorative tribute I trust Roger Morris would have enjoyed and given his approval in principle, if not in detail of execution. Finally, lest so much aseptic levity make you think the subject is not important, I conclude, in all humility, with a verse of scripture (Jeremiah 17:9): "The heart is deceitful above all things. . . . Who can know it?"

COMBINED ANTIBIOTIC THERAPY IN REFRACTORY URINARY TRACT INFECTIONS

George M. Eisenberg, D.Sc., John D. Alexander Jr., M.D.
and
Harrison F. Flippin, M.D., Philadelphia

Comprehensive in vitro studies by one of us (G. M. E.)[1] on the inhibition of various bacteria by antibiotic combinations indicated that a combination of aureomycin, oxytetracycline (Terramycin), and chloramphenicol possessed antibacterial properties that were not evident when these antibiotics were tested singly in equal concentrations against the same organisms. The present study, part of a more extensive project to be reported later, was undertaken to test this combination clinically. In this report, major emphasis will be placed on our experiences in the treatment of selected patients with refractory urinary tract infections. In addition, attention will be directed to the significance of certain factors, which became manifest only after the study had progressed for a time and which we now believe are fundamental to proper clinical evaluation of any antibacterial agent intended for use in this type of infection.

MATERIALS AND METHODS

The antibiotic combination, hereafter referred to as AOC, consisted of pure crystalline aureomycin hydrochloride, oxytetracycline hydrochloride, and chloramphenicol combined in equal proportions on a weight basis. It was dispensed in 0.5 gm. amounts in gelatin capsules. Administration was by the oral route, 2 to 3 gm. daily in divided doses, the larger dose being employed where in vitro tests suggested moderate resistance of organisms. While most of the patients were treated for only 5 days, a few of those with severer cases received courses of from 7 to 10 days.

The series comprised 36 patients divided into three groups as follows: 1. Group A comprised seven patients studied and treated with AOC by the ward staff on the medical service. Specimens for urine culture were obtained by nursing personnel and examined by procedure 1 (described below). 2. Group B was composed of 15 patients on the urologic service, studied by us solely to evaluate the reproducibility of urinary flora in specimens collected by nursing personnel. Specimens from this group were examined by procedure 2. 3. Group C was made up of 14 patients initially studied and treated by the ward staff of the medical service but subsequently studied bacteriologically and treated with AOC by us. Specimens for culture were collected by us. In the case of men, the glans penis was first cleansed with sterile cotton moistened with sterile green soap and the patient instructed to void. The urine initially voided was discarded. The latter portion was collected with care being taken to avoid contact between the glans and the specimen bottle. Female patients were draped in bed, or, whenever possible, on an examining table by a nurse. A catheterization tray, containing sterile towels, metal catheter, specimen bottles, and solution cups, was placed conveniently at hand. After the patient was draped with the sterile towels and the vulva cleansed with sterile cotton moistened with green soap, the metal catheter was inserted and the urine collected by an assisting nurse as it issued from the catheter. A similar technique was employed in catheterizing men. The specimens were examined by procedure 2. All materials used in collecting specimens from patients in this group were prepared and sterilized by personnel of the bacteriology department.

Procedure 1.—One-half milliliter of specimen was transferred aseptically to a tube of blood culture medium and incubated overnight at 37 C. Smears were prepared and stained by Gram's method. Appropriate plating and determinative procedures were applied to the isolated organisms. Antibiotic susceptibility tests were made by the modification of the filter paper disk procedure.[2] Susceptibility to AOC was determined by use of disks saturated with a solution of antibiotic combination so as to contain 1.25, 2.0, and 5.0 mcg. of aureomycin, oxytetracycline, and chloramphenicol, respectively.

Procedure 2.—Fifteen milliliters of specimen was placed in a sterile centrifuge tube and sedimented for 15 minutes at 3,000 rpm. Following decantation of the supernate, one portion of the sediment was serially streaked on blood, bromothymol blue lactose, and SS agar plates. A second portion was distributed with a sterile swab on the surface of a blood agar plate to be used for susceptibility tests. Finally, a third portion was used to prepare smears for microscopic examination. Thus, it was possible to determine the morphology of the bacterial flora in the specimen in a minimal interval of time after collection, correlate the morphological types found on culture with those seen on smear, and ascertain the antibiotic susceptibility of the flora, all within a period of 18 to 24 hours. Thus, if it was desired to check on the constancy of the bacterial flora, it could be done on duplicate specimens within a 36 to 48 hour period.

RESULTS AND COMMENT

Initial Clinical Trial of AOC.—For this purpose, the seven patients in group A were utilized. Tables 1 and 2 present the data pertinent to diagnosis, renal function,

therapy, bacteriology, and results in each of the cases. When an attempt is made to evaluate this data, it is immediately apparent that unequivocal conclusions regarding the effectiveness of the AOC combination cannot be drawn in each of these cases. The reason for this becomes obvious when consideration is given to the bacteria present before and after treatment in relation to the time of institution of the therapy. For example, in case 3 the urine culture before treatment with sulfisoxazole (Gantrisin) showed Pseudomonas aeruginosa and enterococcus. During sulfisoxazole therapy coliform and Proteus organisms were found, while on conclusion of this therapy, coliform, Proteus, and enterococcus organisms were found. On bacterial grounds, it might be concluded that sulfisoxazole treatment had successfully eradicated the Pseudomonas organisms, temporarily eliminated the enterococcus, and induced the appearance of the coliforms. Excluding, at present, the possibility of contamination, such variation in flora might be explicable on the basis of observation by others,[3] that after antibiotic therapy variations in flora are to be expected. A period of four days intervened between the post-sulfisoxazole culture and the start of treatment with AOC, during which time no specimens were collected. The post-AOC culture showed "no growth." There is, thus, a great temptation to claim that the AOC therapy had successfully eradicated the organisms surviving the sulfisoxazole therapy. This conclusion might be justified, provided that the possibilities of contamination were eliminated beyond reasonable doubt. That such an assumption can be frequently unjustified is apparent from consideration of table 3. This shows the variation in flora found in consecutive urine specimens collected at 24 hour intervals from 18 patients (group B) on the urologic service who were not receiving treatment. In 11 of the 15 cases (74%) it was not possible to demonstrate the same urinary bacteriology in two consecutive specimens taken within a 24 hour period. (These patients did not have urethral manipulation or antibiotic therapy.) While the remaining four patients yielded a reproducible flora under the same conditions, one of these (case 21) showed a variation in the third and fourth specimens taken five days later. It seems very unlikely that such an intrinsic urinary flora variation would exist in patients with a stable homeostasis unmodified by internal drug therapy or external urethral manipulation, and, while this possibility has not been entirely eliminated, it seems probable that Barnard and his associates [4] are correct in their view that under these conditions the urinary flora would be expected to remain constant. Any variation observed would most likely be attributable to contamination at the time of obtaining the specimen. It would then seem reasonable to question the significance of the findings on a single urine specimen. If there is doubt in this connection, it is only logical that there should be difficulty in evaluating the effect of a therapeutic agent prescribed in such a case. As an illustration, attention is directed to case 5 (table 1). A single culture taken two days prior to AOC therapy revealed Escherichia coli and enterococcus. A culture taken one day after therapy showed "no growth." Again, there is the temptation to ascribe what appears to be successful eradication of the organisms to the AOC therapy, but this is not completely justified in view of the experiences with variations in the 24 hour flora seen in the cases in table 2. We are forced to conclude that a reliable, unprejudiced evaluation of antibiotic therapy of urinary tract infections depends on unequivocal establishment of the identity of the infecting flora. In our experience, this can be accomplished only through the adoption of the best available techniques, both in the collection and examination of the specimens and by the taking and examining of multiple pretherapy specimens.

Second Clinical Trial of AOC.—With this basic principle in mind, AOC was used to treat the 14 patients in group C. Table 4 shows the data pertinent to diagnosis and renal function in these cases. Table 5 shows that the first five cases, each showing a single organism susceptible in vitro to AOC, cleared of bacilluria, pyuria, and fever. This was accomplished in four cases, with a total of 10 gm. of the combination over a five day period; one patient received 14 gm. in a seven day course. In two of the cases, no antibacterial therapy preceded the AOC; the other three patients had received penicillin (crystalline and/or procaine), streptomycin, sulfisoxazole, or sulfadiazine, at one time or another during the period preceding AOC therapy.

In the second group of four cases (table 6), each showing a single organism susceptible in vitro to AOC, the bacteria found before AOC were eliminated only to be replaced, after cessation of this therapy, by generically dissimilar organisms; however, pyuria and fever where present were also eliminated. The nature and distribution of this post-AOC flora was as follows: 1. Micrococcus species only, two cases each treated with 2 gm. of AOC daily for five days. 2. Proteus species only, one case of Salmonella choleraesuis bacilluria treated with 20 gm. of AOC in a 10 day period. There was evidence in this case that the finding of Proteus micro-organisms was associated with traumatic cystitis, probably resulting from excessive urethral manipulation. 3. Micrococcus and Proteus species, one case treated with 3 gm. of AOC daily for five days.

In all of these cases, no antibacterial therapy preceded the AOC combination. Cases 32 and 33, shown in table 7, are characterized by the fact that in both the infecting organism isolated prior to AOC therapy was temporarily eliminated by it but recurred shortly after its cessation. Both patients had received penicillin prior to AOC, the patient in case 32 receiving almost 29 million units in an 11 day period, while the one in case 33 was given almost 10 million units in 12 days, for 10 of which 33 gm. of sulfisoxazole was given additionally. The failure of 15 gm. of AOC to permanently clear the Pseudomonas from the urine in case 32 may have been due to the fact that this organism was found to be moderately resistant to an AOC concentration equivalent to that which might have been expected on a 3 gm. per day, five day dosage schedule. It would have been interesting to determine whether a second, more prolonged course of AOC would have produced a more permanent bacteriological remission. This could not be attempted because of the patient's desire to return home. The bacteriological relapse seen in case 32, despite susceptibility of the organism, is explicable on the basis of anatomic obstruction (stricture) and the short therapeutic course, 8 gm. in four days.

[4] Barnard, D. M.; Story, R. D., and Root, H. F.: Urinary Tract Infections in Diabetic Women, New England J. Med. **248**: 136-141, 1953.

The final group of three patients (cases 34, 35, and 36) are characterized by urinary tract infections caused by multiple, mixed bacteria, of which at least one member was found to be resistant to AOC in vitro. In spite of this, these patients were treated with AOC for two reasons: 1. All other therapies employed had failed to produce the desired response. 2. There was a possibility that through the elimination of the AOC-susceptible members the remaining flora might likewise disappear as a result of distortion in the microbiological balance. That neither of these ends was accomplished is evident from the results. In case 34 the susceptible Klebsiella micro-organisms were eliminated, only to be replaced by micrococci; resistant Proteus persisted. In case 35 AOC therapy eliminated the susceptible Pseudomonas and had no effect on the insensitive Proteus and paracolon microorganisms. In passing, it is well to point out that these same organisms were not eliminated by a three day subsequent course of streptomycin. In both of these cases the organisms eliminated by the AOC therapy had failed to be removed by 9 million units of penicillin (case 34) and 26 gm. of aureomycin (case 35). Far advanced renal functional impairment may have been a contributory factor in this case. The therapeutic failure of AOC in case 36 can be ascribed to the age, general debilitation, and diminished renal blood flow, secondary to congestive failure. Similar therapeutic failure was experienced following courses of combinations of procaine penicillin sulfisoxazole and sulfadiazine-streptomycin.

CONCLUSIONS

In summarizing our impression of the merit of the AOC combination, we acknowledge that follow-up examinations are essential for the determination of permanency of cure in these cases. In this respect, serious limitations are imposed when dealing with patients usually seen in a large municipal hospital for the indigent. In spite of the comparative brevity of the follow-up interval in our cases, we nonetheless feel that certain conclusions can be justifiably made.

In five patients there was complete disappearance of all bacteriological and clinical evidence of the urinary tract infection, which had been refractory to previous medication. In four patients there was complete disappearance of all clinical evidence of urinary tract infection. In these cases the responsible pathogen was eliminated only to be replaced by other organisms, the pathogenicity of which is doubtful in view of the improvement in clinical status and in collateral urinary studies. In two patients there was complete disappearance of clinical evidence of disease but only temporary removal of the offending pathogen. In three patients it was not possible to gage clinical effectiveness because of the lack of characteristic signs and symptoms before therapy. In two of these, with mixed pathogens, the susceptible organisms were eliminated. The third was a therapeutic failure, age and general debilitation contributing to the result. Toxic manifestations, such as nausea, vomiting, and diarrhea were not apparent in the doses used.

AOC combination was effective against such organisms as Klebsiella pneumonia type A, other Klebsiella species, coli-aerogenes, Salmonella choleraesuis, enterococcus, Pseudomonas aeruginosa, and Micrococcus pyogenes var. aureus. The appearance of bacterial opportunists, Micrococcus species in our cases, is not peculiar to AOC therapy. This phenomenon, involving other organisms, has been observed frequently following use of other antibiotics.[5]

SUMMARY

The results of treatment of refractory urinary tract infections with a combination of aureomycin, oxytetracycline (Terramycin), and chloramphenicol (AOC) are presented. While the number of cases treated under controlled conditions that permit unequivocal evaluation of the therapy was small and the follow-up period of short duration, results suggest that this combination has merit and is worthy of additional clinical study. Evidence is presented to demonstrate the desirability of multiple pretherapy cultures in order to permit objective evaluation of antimicrobic therapy.

Subphrenic Infections.—In subphrenic infections the safety and recovery of the patient depends to a great extent on the correct diagnosis being made. It can usually be diagnosed if the possibility of its existence is kept in mind. In any patient with an unexplained fever, and especially following abdominal suppuration, the likelihood of subphrenic infection should be considered. . . . Subphrenic infection results in a fever of the swinging type and general toxic signs and symptoms which may result in rapid deterioration in the patient's general condition. The patient may complain of pain or discomfort in the upper abdomen or over the lower ribs posteriorly. Tenderness on pressure may be present but its absence by no means excludes the infection. As a rule the tenderness is in relation to the 12th rib posteriorly, or below the costal margins in anterior space infections. The most useful and constant physical sign is some limitation of movement, on respiration, of the lower part of the chest on the affected side. This is usually most easily detected from behind and is due to limitation of diaphragmatic movement on the affected side. Apparent increase in the liver dullness may be noticed. There may be signs of a basal pleural effusion, usually of a sympathetic nature, on the affected side or of basal lobular pulmonary atelectasis. The white blood count, not unnaturally, shows a polymorpho-nuclear leucocytosis. The most useful aid to diagnosis is the use of x-rays, and examination under the fluorescent screen is usually more valuable than by means of films. The most constant x-ray finding is that the diaphragm is raised on the affected side and that the range of movement on respiration is diminished compared with the normal side. It may be possible to see an accumulation of gas in the upper part of the subphrenic abscess with a horizontal fluid level below it, but this is not nearly so common as writers in the past have tended to suggest. The gas is usually due to the fact that the subphrenic abscess has communicated with a hollow viscus, such as in the case of perforated peptic ulceration, rather than to the presence of gas-forming organisms within the abscess.—A. B. Birt, M.D., Subphrenic Infection, *Postgraduate Medical Journal,* May, 1953.

FLUID AND ELECTROLYTE DISTURBANCES IN PROSTATISM

Jack Lapides, M.D., Ann Arbor, Mich.

During the past decade or two great strides have been taken in reducing the morbidity and mortality associated with the treatment of prostatism. This progress has been attributed to earlier diagnosis, improved surgical techniques, introduction of modern antibiotic and chemotherapeutic agents, liberal use of whole blood, and, more recently, employment of fluid and electrolyte repair solutions. Since metabolic disorders are relatively frequent in the patient with urinary retention, it is apparent that fluid and electrolyte imbalances are common and important problems. In order to treat these disturbances rationally, one must have a knowledge of the role played by the kidney in the pathogenesis of the electrolyte disorders, as well as a comprehension of its clinical and laboratory manifestations. In this discussion an attempt will be made to indicate the causes of the electrolyte disorders, the types of imbalances most frequently encountered, and the rationale for the use of particular repair solutions.

EFFECT OF BACK PRESSURE ON RENAL FUNCTION AND STRUCTURE

Complete or partial obstruction of the lower urinary tract by an enlarged prostate results in urinary retention. The accumulation of urine in the bladder raises the intravesical pressure, which in turn leads to an increase in intraureteral and intrapelvic pressures. The increased pressure is reflected up the infundibula, calices, and tubules of the nephrons. Since effective glomerular filtration pressure is the difference between the intravascular hydrostatic pressure on the one hand and the sum of the osmotic pressure of the plasma proteins and the intrarenal tissue pressure on the other,[1] it will be observed that the increase in intrarenal tissue pressure produced by the urinary retention will result in decreased glomerular filtration (fig. 1). Glomerular filtration will be impaired further because of decreased blood flow due to compression of the blood vessels by the increased intrarenal tissue pressure.[2] Tubular function will be disturbed also [3] because of a decrease in the peritubular capillary blood flow, which is due to compression of the vessels by increased intrarenal pressure.

If the urinary retention is of short duration, it is probable that no structural changes will occur; however, prolonged lower urinary tract obstruction will result initially in anemic and pressure atrophy of the tubules. Later, the glomeruli will be destroyed so that the kidneys in the end stage become connective tissue shells.[4] It has been demonstrated experimentally in animals [4] that removal of the back pressure will result in structural repair and restoration of function, the degree being dependent on the period of obstruction. In man, following drainage of the bladder, improvement has been observed to take place in both glomerular and tubular function [5]; the function of the tubules, however, appears to recover to a greater extent. The period of time necessary for maximal improvement may be one to two months in some instances.

ELECTROLYTE DISORDERS

Mechanism.—In the healthy person normal renal function serves to maintain a relatively constant environment for the cells of the body so that they can carry out their appropriate activities in a normal manner. Impaired kidney function will lead to aberrations in the chemical structure of the plasma, the interstitial fluid and the intracellular fluids, with resultant serious disturbances in cellular functions. These cellular dysfunctions then manifest themselves by such clinical signs and symptoms as nausea, vomiting, anorexia, ease of fatigue, and anemia.[6]

Normally the kidneys help to maintain homeostasis by "screening the blood plasma" continuously, i.e., the renal nephron deletes the blood plasma of substances that are in too great a concentration and attempts to retain most of any material that is approaching subnormal levels. For example, the kidneys tend to retain most of the glucose, sodium, chloride, bicarbonate, and water that is filtered but seek to excrete the larger portion of sulfates, phosphates, urea, creatinine, and uric acid. It is apparent that the waste products of protein catabolism (sulfates, phosphates, and nonprotein nitrogen) are excreted while the substances necessary for cellular building and activity are retained. Other considerations that govern the kidneys' activities are the necessity for maintaining a blood pH of 7.4 and a plasma volume of approximately 3,000 cc. Before discussion of the types of electrolyte disturbances encountered in urinary retention, it would be well to emphasize that more than 60% of the patients seen with prostatism do not have fluid and electrolyte abnormalities.[7]

Group 1.—The first group to be considered includes patients who have had urinary retention for a relatively short period of time and in whom little or no renal structural damage has occurred. In accordance with the mechanism described previously, these patients will have diminished glomerular filtration because of back pressure due to urinary retention. Impairment of glomerular filtration will lead to retention of all substances in the body; however, only those materials that are not needed by the body and are destined for excretion, namely, sulfates,

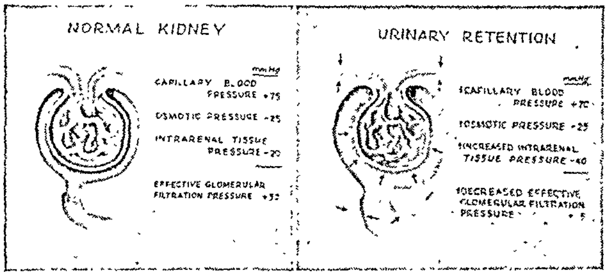
phosphates, and nonprotein nitrogen, accumulate rapidly in the body; the nonprotein nitrogen level is the first to become elevated. Thus in the severest case in this group there might be a blood nonprotein nitrogen level of 70 to 80 mg. per 100 cc., a normal plasma protein level, normal values for sodium, potassium, and calcium, slightly elevated phosphorus, sulfate, and organic acid levels, and a slightly decreased plasma bicarbonate level (fig. 2).

The patients placed in group 1 usually do not have such symptoms and signs as nausea, vomiting, and anemia. They are dehydrated occasionally, because many persons believe that bladder distension and frequency of urination will be decreased if fluid intake is decreased.

Group 2.—The second group to be discussed includes patients who have had prolonged urinary retention and whose kidneys have been damaged structurally as well as functionally. Many of these patients have symptoms of nausea, vomiting, anorexia, and ease of fatigue. Some will be agitated and disoriented while others may be stuporous. Hyperpnea and dyspnea may be present. They will often have signs of dehydration or extracellular fluid volume deficiency.



NORMAL KIDNEY

DECREASED EFFECTIVE GLOMERULAR FILTRATION PRESSURE +5

Fig. 1.—Comparison of normal kidney and kidney in urinary retention, showing how the increase in intrarenal tissue pressure in urinary retention results in decreased glomerular filtration.

Unfortunately, there is no one electrolyte profile that is typical of this group. This is in accordance with the findings of Peters and associates,[8] who found no constant ionic plasma pattern in diseased kidneys of various types. One can state, however, that in this second group the plasma bicarbonate level is always below normal; phosphate, sulfate, and frequently organic acid levels are elevated to above normal; and the nonprotein nitrogen value is always increased. The plasma protein sodium, total base, and calcium levels may be normal or decreased. Potassium and chloride values may be elevated, normal, or decreased. It will be observed readily, therefore, that correction of fluid and electrolyte imbalances in this group of patients must be individualized.

It has been assumed arbitrarily that after appropriate treatment the two groups that have just been discussed will have normal electrolyte patterns and will be able to undergo definitive treatment, namely, prostatectomy. There are some patients who do not fall into the previous two categories, since they will never come to operation because of far-advanced renal insufficiency. These patients will demonstrate electrolyte and fluid disturbances similar to those of the second group but, unlike the second group, will show little improvement with therapy.

THERAPY

Drainage.—Since back pressure due to urinary retention is the chief cause of renal impairment in prostatism, it is obvious that prompt relief of the urinary retention must be obtained. Bladder drainage will not only halt further renal deterioration but will result in considerable improvement in kidney function and structure.[9] Urethral catheter drainage is quite adequate for all of the patients in group 1 and for the mild cases in group 2. Suprapubic cystostomy, however, is the appropriate type of urinary drainage for the severe cases in group 2 and for all of the patients in group 3, since prolonged catheter drainage will be necessary for these patients before definitive surgery can be contemplated. The incidence of urethritis, epididymitis, and acute pyelonephritis is much less with suprapubic drainage than with urethral catheter drainage. Acute pyelonephritis superimposed on an already impaired kidney is often enough insult to cause death.

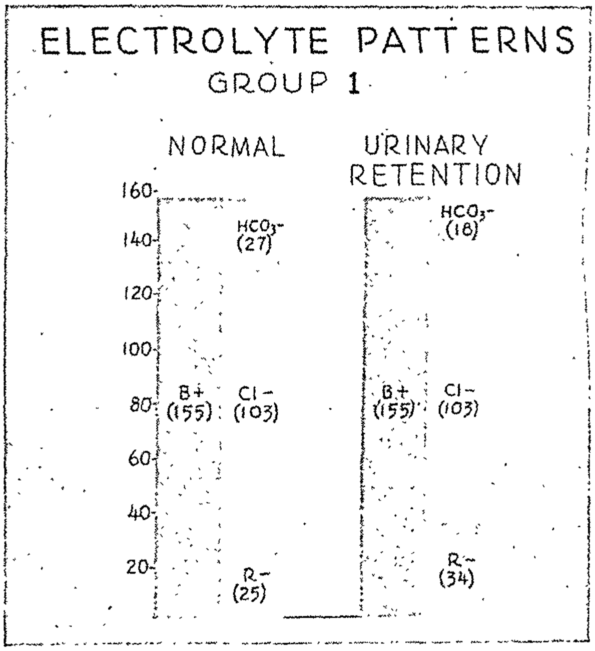

Fig. 2.—Electrolyte patterns in normal persons and in patients who have had urinary retention for a relatively short period of time, with little or no renal structural damage (group 1).

Restoration of Chemical Balance.—In addition to urinary drainage, adjustment of the ionic pattern and fluid volumes of the vascular, interstitial, and intracellular compartments to a normal state is necessary. This requirement is apparent when it is realized that the patient's symptoms are due to abnormal cellular function, which in turn is caused by aberrations in electrolytes and fluids.

In estimating the type and quantity of solution to be used, one must be guided by both laboratory and clinical data. Since most hospitals have limited laboratory facilities, determination of the plasma bicarbonate, chloride, calcium, phosphorus, and nonprotein nitrogen levels will usually suffice as the basic laboratory data. Evaluation of the state of the extracellular fluid volume is based to a great extent on clinical signs.[10] A marked deficit in extracellular fluid volume is characterized by (1) apathy, (2) anorexia, (3) illeus, (4) orthostatic hypotension, (5) tachycardia, (6) softening, shrinking, and longitudinal wrinkling of the tongue, (7) enophthalmos, (8) softness of muscles, and (9) below normal temperature.

[9] Hinman.[4] Lich.[5]

[10] Moyer, C. A.: Fluid Balance: A Clinical Manual, Chicago, The Year Book Publisher, Inc., 1952, p. 68.

A patient may be markedly dehydrated by loss of fluid without necessarily losing electrolytes. In this instance the patient will show thirst, dry mucous membranes, red swollen tongue, flushed skin, fever, tachycardia, and hypotension in addition to softening of the muscles, enophthalmos, and sticky skin. Dehydration of the types just described are the ones most commonly present in the patient with prostatic disease when he first presents himself to the physician.

Treatment of the patient who has had urinary retention for a short period of time (group 1) is a rather simple matter. His blood chemistry studies will indicate elevated nonprotein nitrogen, slightly decreased plasma bicarbonate, elevated plasma chloride, and slightly increased phosphorus levels. Clinical examination will demonstrate dehydration, with an increase in osmolar concentration of electrolytes or, more simply, loss of extracellular fluid without loss of electrolytes, thus resulting in an increased concentration of the electrolytes in the blood plasma and interstitial fluid. This type of dehydration takes place when the patient in urinary retention does not drink or eat. He may have dry sticky mucous membranes, a swollen tongue, flushed skin, fever, and tachycardia. Therapy consists of urethral catheter drainage and forcing fluids if the patient is not nauseated. If the patient is nauseated, approximately 3,000 cc. of 5% glucose in water given intravenously over a period of four to five hours will satisfy the initial 24 hour requirement for fluids. Solutions containing electrolytes are not indicated, since an increased osmolar concentration of electrolytes is already present; in addition, the metabolic acidosis is mild and will be corrected as soon as glomerular filtration is increased. The therapy advocated is aimed specifically at increasing glomerular filtration, in that the back pressure is removed by bladder drainage and the plasma volume is increased by the glucose solution. In addition, the glucose itself is of value, since it promotes diuresis as well as spares the further breakdown of body protein, the end products of which have been partial contributors to the azotemia and acidosis. Most of the patients will be taking fluids and food orally by the second day so that further parenteral therapy may not be necessary. The 24 hour urinary output should be maintained at a minimum of 2,000 cc. If it falls below the minimum, oral fluid intake should be supplemented with 1 to 2 liters of 5% glucose in water parenterally. With this therapy the patient should be ready for operation within three days.

The patients who have been in partial or complete urinary retention for a prolonged period of time present a more difficult problem in treatment. Because of longstanding azotemia and acidosis, they are usually malnourished, dehydrated, anemic, and in poor general physical condition. Blood chemistry studies in a typical case may reveal a nonprotein nitrogen level of 200 mg. per 100 cc., plasma bicarbonate level of 15 mEq. per liter, plasma chloride level of 95 mEq. per liter, and serum calcium level of 4 mEq. per liter. The serum potassium levels in these patients are frequently above normal before urinary drainage and fluid therapy, although there may actually be a decreased concentration of potassium intracellularly. Physical examination of the patient may disclose evidences of dehydration and uncompensated metabolic acidosis, namely, hyperpnea and dyspnea.

After the history has been taken, the patient examined, and emergency blood chemistry studies accomplished, therapy is indicated. If the patient has an inlying urethral catheter when first seen, suprapubic cystostomy is postponed for several days. If the patient has not been catheterized previously, then he is subjected immediately to a suprapubic cystostomy under local anesthesia. Fluid and electrolyte therapy is started as soon as possible.

Analysis of the hypothetical case described reveals that the patient has (1) uncompensated metabolic acidosis, (2) extracellular fluid deficit or dehydration, and (3) probable normal osmolar concentration of electrolytes. Normally the sum of plasma chlorides (103 mEq.) and plasma bicarbonate (27 mEq.) should equal 130 mEq. per liter. In the case described the chlorides (95 mEq.) and bicarbonate (15 mEq.) totaled only 110 mEq. per liter. It would seem then that the osmolar concentration of electrolytes is less than normal. It must be remembered, however, that in prostatism with urinary retention the organic and inorganic acids accumulate in the extracellular fluid, combine with the available sodium, and thus cause a decrease in plasma bicarbonate (fig. 3). Thus the osmolar concentration of sodium may still be within normal limits. Occasionally a patient is found to have a decreased plasma concentration of electrolytes, as illustrated in figure 3.

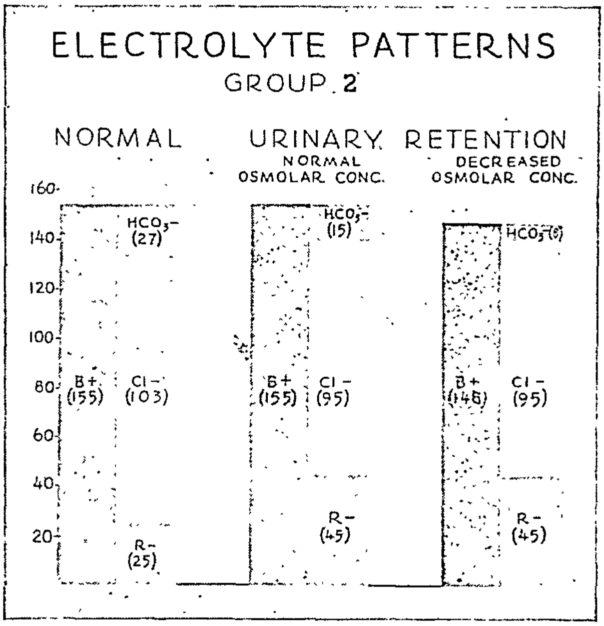

Fig. 3.—Electrolyte patterns in normal persons and in persons who have had prolonged urinary retention, with resultant structural as well as functional damage (group 2).

The solutions to be selected, then, should correct the acidosis, bring the extracellular fluid volume up to normal, inhibit further tissue breakdown, and promote diuresis. A liter of 1/6 molar sodium lactate is usually enough to compensate the metabolic acidosis so that the hyperpnea disappears. When sodium lactate is administered to a patient with hypocalcemia and acidosis, the patient should be observed closely for signs of tetany. If he shows such signs as carpopedal spasm or positive Chvostek's sign, then 10% calcium gluconate should be administered intravenously until the signs disappear.

The liter of sodium lactate should then be followed by 2 liters of a mixture containing one part of 1/6 molar sodium lactate and three parts of isotonic sodium chloride solution. This mixture closely resembles interstitial fluid and will serve to build up the extracellular fluid volume as well as to aid in correcting the acidosis.

Two liters of 5 or 10% glucose in water should then be given to provide for insensible loss of water, urinary water, diuresis, and sparing of protein catabolism as well as prevention of starvation ketosis. In most instances the fluids mentioned can be given intravenously at a rate of about 500 cc. per hour. If necessary, any isotonic electrolyte solution can be given subcutaneously or intramuscularly.

Many patients with decreased plasma bicarbonate levels do not have hyperpnea or dyspnea, i.e., their acidosis is compensated. In these cases it is better to correct the acidosis with a mixture of three parts isotonic sodium chloride solution and one part 1/6 molar or isotonic sodium lactate solution.[11] The serum bicarbonate level is restored at a slower rate than with 1/6 molar sodium lactate alone, but the lactate-chloride mixture serves to restore fluid volume deficits in addition to correcting the acidosis. Furthermore, the risk of inducing tetany with hypocalcemia is considerably less with the use of a lactate-chloride mixture.

It should be emphasized that electrolyte solutions are to be utilized primarily for correction of electrolyte distortions, disturbed electrolyte concentrations, and fluid volume deficits. The electrolyte solutions should not be used as a source of water to compensate for loss through the urine, lungs, and skin. Five or 10% glucose in water solution is the ideal fluid for supplying water parenterally. Occasionally, one encounters instances wherein large amounts of glucose solution have been used in an attempt to correct fluid volume deficits associated with decreased plasma electrolyte concentrations. The attempts invariably meet with disaster, since water intoxication is usually produced. The solution first enters the extracellular compartment and causes a marked dilution of the electrolytes present. Because of the hypotonicity that is produced, water will shift from the interstitial fluid into the cells, causing extracellular dehydration and intracellular overhydration. This will result in nausea, vomiting, muscle twitching, salivation, lacrimation, and oliguria.[10]

It cannot be emphasized too strongly that there is no one formula or group of formulas that can be used in determining the type and amount of fluid to be given in a particular case. Constant clinical and chemical evaluation of the patient is the only safe method of determination; however, there are a few generalizations that can be used as a rough guide in parenteral fluid therapy of the prostatic patient with urinary retention.

1. Adequate therapy can be carried out in most of the patients with the use of essentially two solutions. They are a 5 or 10% solution of glucose in water and a mixture of three parts isotonic sodium chloride and one part 1/6 molar sodium lactate solutions.

2. The chloride-lactate mixture is used to correct extracellular fluid volume deficits as well as acidosis. The glucose water solutions serve to provide water for urine and insensible loss of water through skin and lungs.

3. One-sixth molar sodium lactate solution is administered only when a patient demonstrates uncompensated metabolic acidosis characterized by dyspnea and hyperpnea; and it is used only in a quantity sufficient to dissipate the hyperpnea. The remaining compensated acidosis is treated with the chloride-lactate solution.

4. If the patient's glomerular filtration is improving as evidence by decreasing blood nonprotein nitrogen, then potassium therapy is started on the second or third day of parenteral feeding. A total of 4.0 gm. of potassium chloride per day is sufficient to prevent hypokalemia. The potassium can be given in the glucose-water solution in a concentration of 2.0 gm. of potassium chloride per 1,000 cc. of 5% glucose in water solution.

5. Except during the first 48 hours, when a large deficit of electrolyte is being replaced, the usual daily volume of fluids will not exceed 3,500 cc. One liter of the fluids is chloride-lactate mixture and 2.5 liters are glucose-water solution.

Wilson, Reisman, and Moyer [12] have studied a number of patients with chronic urinary retention in whom marked salt and water depletion developed following decompression of the bladder. They found that the depletion was due to marked losses in the urine (as is commonly seen in the recovery phase of acute renal injury). Fortunately, this type of response has been quite rare in our experience. Treatment should consist of replacement of the salt and water losses with lactate-chloride mixture until the kidneys have recovered.

After parenteral administration of fluids is no longer necessary, the patient should be observed carefully for signs of renal tubular insufficiency, which may manifest itself in polyuria, persistent hypochloremia, hyperchloremic acidosis, or hypochloremic acidosis. If the patient has nephritis in which he is losing sodium chloride without acidosis, he should have a daily intake of 2 to 4 gm. of sodium chloride in addition to the usual amount of sodium chloride in his diet. If the base-conservation mechanism of his tubules is not producing ammonium and hydrogen ions, then sodium bicarbonate, 3 to 4 gm. per day, should be prescribed. Both sodium chloride and bicarbonate are indicated if hypochloremic acidosis tends to develop.

The type of patient found in group 2 is not subjected to prostatectomy until the kidneys are able to maintain homeostasis. As stated previously, in some cases cystostomy drainage may be necessary for six weeks before the azotemia and acidosis have completely disappeared.

The patient can usually be sent home to complete his recovery process once he is well started on oral feedings. If the patient's serum calcium is low and phosphorus high, calcium lactate, vitamin D, aluminum hydroxide gel (Amphojel) and Shohl's solution (containing 98 gm. of sodium citrate and 140 gm. of citric acid per liter of distilled water) can be prescribed. The aluminum hydroxide gel serves to prevent absorption of phosphorus from the intestine and thus will tend to reduce the serum phosphorus. Shohl's solution is used to aid in absorption of calcium lactate from the intestine and also to provide available base to the body.[13]

SUMMARY

Lower urinary tract obstruction by an enlarged prostate often leads to aberrations in the fluid and electrolyte balance of the body. The role of back pressure in the production of the renal dysfunction leading to electrolyte abnormalities is discussed. An outline of the types of electrolyte problems encountered in patients with urinary retention is presented. The various repair solutions utilized in the correction of the electrolyte disturbances and the rationale for their use are indicated.

FLUID AND ELECTROLYTE BALANCE IN BURNS

Capt. Eric Reiss, Lieut. Jerry A. Stirman, Major Curtis P. Artz, Capt. John H. Davis
and
Col. William H. Amspacher, (MC), U. S. Army

No insult to the body equals a burn in intensity. A severe, untreated burn causes death by initiating incredibly large and rapid shifts of fluids. In burns as well as in other conditions associated with fluid derangements, present day therapy is based on the assumption that optimal care consists of the administration of fluids at the same rate and in the same volume and composition in which they are lost. For instance, the best therapy for a patient who loses 500 cc. of blood during an operation is the administration of the same quantity of blood as rapidly as it is being lost.

During the past 10 years, experimental and clinical data have yielded valuable information concerning the volume and rate of fluid losses in burns. Knowledge concerning the composition of fluid losses in burns remains fragmentary, however, and, to a large extent, conjectural. Treatment is correspondingly imperfect. Despite the progress that has been made in the initial treatment of burns, most patients who have deep burns over more than 50% of the body surface still die. Death in many of these patients is a direct result of fluid and electrolyte shifts. In contrast, less severely burned patients generally respond well to present day treatment.

The purpose of this presentation is (1) to review briefly and critically some facts and speculations concerning the fluid and electrolyte shifts in the severely burned patient and (2) to outline a regimen that has proved valuable in the treatment of a large series of patients.

PHYSIOLOGICAL CONSIDERATIONS

Volume of Fluid Losses.—The volume of fluid lost from the blood and from the interstitial fluid of unburned tissues depends largely on the extent of body surface burned and the depth of the burn. The total surface area involved is best expressed in terms of percentage of body surface and can best be ascertained with sufficient accuracy by the use of the "Rule of Nines." According to this rule, the body is divided into areas representing 9% of the body surface or multiples thereof, as follows: the head 9%; each upper extremity, 9%; each lower extremity, 18%; the anterior trunk, 18%; and the back, 18%. This simple means of rapidly estimating the extent of a burn is extremely valuable and should be committed to memory by every physician.

That the fluid losses (and therefore the fluid requirements) of burned patients are definitely related to the extent of the burn was established beyond doubt by the work of Cope and Moore; their documented experience forms the foundation on which modern treatment is based.[1] The depth of burn as a factor determining fluid losses is equally important but not as well appreciated by the medical profession. Burns injure tissue cells and capillary walls. The intensity of the heat source and the duration of the tissues' exposure to heat determine the depth of burn and the total quantity of tissue damaged in any particular area. Although the true depth of a burn defies clinical diagnosis, it is certain that skin is not the only tissue that is affected by burning. In partial thickness burns (second degree), the epithelium is incompletely destroyed, yet capillary injury extends well into the subcutaneous tissue. Full thickness burns (third degree) can be associated with widespread, deep tissue injury that profoundly influences the fluid needs of the patient. The severity of injury ranges from necrosis in the more superficial structures to less severe damage in tissues that are farther removed from the source of heat. It is well, therefore, to think of a burn as three dimensional trauma rather than as trauma that involves merely the surface. Unfortunately, inspection of a burn frequently yields a misleading impression of the magnitude of fluid losses. The exudate that weeps so copiously from the surface of a recent partial thickness burn is but a small fraction of the total loss: the major loss occurs in the tissues and is concealed from vision until the wound begins to swell a few hours after injury. In full thickness burns, visible exudation is completely absent, and the hard, dry, eschar, which is characteristic of full thick-

ness injury, often prevents swelling. Nevertheless, it is this type of injury with a dry surface that poses the most vexing problems and is in need of more intensive supportive therapy than the profusely oozing partial thickness burn.

Rate of Fluid Losses.—The most rapid loss of fluids occurs in the first few hours after burning. By the sixth to eighth hour, a large portion of the fluid losses has occurred; thereafter, the rate of loss is sharply reduced. When wound edema reaches a maximum in approximately 48 hours, fluid losses into the wound virtually cease. Clinically, the rapid infusion of fluids during the first six to eight hours and the subsequent decline in the rate of fluid administration has proved very effective.

Composition of Fluid Losses.—The problem of the composition of fluid losses bears an important relationship to the nature and location of fluid shifts. An abundance of experimental work has failed so far to elucidate this crucial problem. Only this much is clear from what has already been said about the three dimensional character of the burn wound: burn exudate must be a mixture of heterogeneous fluids. Varying degrees of capillary and tissue damage must result in fluid losses of varying composition.

Proteins: From inspection of blister fluid it might be surmised that burn exudate resembles plasma. With the use of radioactive dyes, Cope and Moore proved that the capillaries in burned areas are abnormally permeable to proteins.[2] In subsequent studies, Cope and associates studied the concentration and partition of proteins in the lymph and plasma of burned dogs.[3] They noted an early increase in the plasma protein concentration and a high albumin-globulin ratio in the lymph. The increasing plasma protein concentration indicated a more rapid loss of water than of proteins, and the high albumin-globulin ratio in the lymph pointed toward the more rapid loss of the smaller albumin molecules than of the larger globulin molecules. This important series of experiments forms the rational basis for the use of colloid solutions in the early treatment of burns.

Electrolytes: Unfortunately, the true composition of burn exudate is reflected neither in lymph nor in blister fluids. A study of lymph may give a clue as to the composition of the interstitial fluid in burned areas, but some evidence has been adduced that shows that the injured tissue cells play an important and active part in the fluid shifts. When Fox burned mice and analyzed the burned as well as unburned tissues, he noted the extrusion of potassium and accumulation of sodium in the burned tissues and the uptake of potassium and release of sodium in the unburned tissues.[4] The loss of sodium into the burned tissues was so great that it could cause hypotonicity of the extracellular fluid, which in turn would result in the shift of large quantities of water into the cells of unburned tissues. If Fox's interpretation of his data is correct, large volumes of fluid could be lost not only at the site of burn but also in uninjured regions away from the area of injury. Indirect support of fluid losses remote from the burn is furnished by the experiments of Scott, who was unable to correlate the volume of fluid that accumulated in the area of injury with the death or survival of experimental animals.[5] The effectiveness of salt solutions in the treatment of burned rodents has been established.[6] Evidence regarding the relative effectiveness of isotonic and hypertonic salt solutions is conflicting. In man, the limits of effectiveness of salt solutions has yet to be defined, but it appears certain that most patients who have burns involving 20 to 25% of the body surface can be adequately treated by the use of salt solutions without colloids.

Red Cells: Red cell destruction occurs to a variable extent after burning. Many red cells that are trapped in the area of burn are directly destroyed by heat. Some escape direct destruction but become more fragile and succumb subsequently (delayed hemolysis).[7] The phenomenon of sludging, which has been described by Brooks, may also contribute to the functional removal of large numbers of red cells from the circulation.[8] The magnitude of red cell lysis is largely dependent on the depth of burn: it is greatest in deep, extensive burns and, for practical purposes, insignificant in partial thickness burns, even in those that extend over large areas of the body surface.

Therapeutic Implications: Because our understanding of the pathological physiology of burns is incomplete, our present treatment of the fluid and electrolyte shifts is not altogether satisfactory. Our competence is greatest in appraising the volume and rate of fluid losses; it is least in appraising their composition.

Plasma proteins are of importance in the maintenance of a normal circulating volume and, since they are lost into the burn tissues, their replacement in some form or another appears necessary. The plasma protein concentration in severely burned patients almost always decreases to 5 gm. per 100 cc. or less, regardless of the quantity of blood and plasma that is given. As long as the injured capillaries permit leakage of colloidal particles into the interstitial spaces of burned tissues, the administration of colloid solutions is probably of only limited value in increasing the circulating volume.

Solutions that contain sodium are certainly required in treatment, but it remains to be conclusively shown whether these solutions are by themselves capable of maintaining the blood volume in extensive, deep burns in man. It is possible that massive infusions of solutions containing sodium result in the mobilization of protein stores from the interstitial spaces of unburned tissues and from other stores and that sufficient protein enters the circulation from these sources to sustain the circulating volume.

Only this much appears certain at this time: Electrolytes, whole blood, and colloids are required in the treatment of severe burns. Selection of fluids as regards their composition and total and relative volumes is influenced by the severity of injury and by the physiological status of the patient.

TREATMENT

General Considerations.—All of the mechanical and pharmacological means that have been used in an attempt to decrease the abnormal capillary permeability in burned tissues have failed to influence the loss of fluids. In a series of carefully controlled experiments, Rhinelander observed that compression of the burn wound does not appear to limit the total fluid losses but merely to translocate the losses from the burn wound to the surrounding tissues.[9] This negative evidence is of practical importance, since pressure that is applied over the burn wound in an effort to limit extravasation of fluid may cause serious impairment of circulation in the affected part. Although corticotropin and cortisone influence capillary permeability in areas of inflammation, their ineffectiveness in limiting the leakage of proteins from the capillaries of the burned tissues has been demonstrated, experimentally and clinically.[10]

Although the extent and depth of the burn are by far the most important factors determining the fluid requirements, other factors, including the age of the patient and the location of the burn, must also be taken into account in any plan of therapy. In contrast to the experience of others, our limited experience in the treatment of burned children has indicated that they generally respond well to treatment in the early postburn period. Investigators who have had experience in the treatment of elderly patients have stated that those 60 years of age or older have less chance for survival than younger patients.

It is well to define again the limitations imposed by treatment based on our inadequate understanding of fluid shifts: patients who have third degree burns of more than 50% of the body surface rarely survive for more than 10 days, even under the most skillful medical supervision. The principal factor determining survival appears to be the extent of third degree involvement rather than the total area burned.

Replacement Solutions.—A well-cooled solution containing 3 gm. of sodium chloride and 1.5 gm. of sodium bicarbonate per liter can be administered orally and is well tolerated by most patients.[11] This solution contains only 70 mEq. of sodium per liter and is, therefore, hypotonic with respect to this ion. Isotonic electrolyte solutions, orally administered, are unpalatable and poorly tolerated.

Since a 0.9% solution of sodium chloride contains an excessive concentration of electrolytes, particularly chloride, some type of "balanced electrolyte solution" is preferred in the treatment of burns as well as in the treatment of most conditions associated with a deficit of extracellular fluid volume. Lactated Ringer's (Hartmann's) solution is an acceptable solution that contains, in addition to minute amounts of other ions, 130 mEq. of sodium and 109 mEq. of chloride per liter. The high concentration of available bicarbonate in lactated Ringer's solution offsets the tendency towards acidosis that is frequently seen in the early postburn period. If isotonic sodium chloride solution is used exclusively to meet the sodium requirements of an extensively burned patient, low plasma levels of bicarbonate and very high levels of chloride are frequently encountered.

Colloid Solutions.—Plasma, plasma expanders, and blood are the colloid solutions most commonly used in burns. Plasma that is available to the armed forces causes viral hepatitis of the homologous serum type in a high percentage of patients. In our experience, hepatitis occurred in one out of every five patients who had received plasma, and we have recently observed two fatalities from this complication. For this reason, we never use plasma. Experience with dextran, polyvinylpyrrolidone, and the gelatins indicates that the colloid effectiveness of these plasma expanders is equal or superior to that of plasma.

Signs and Symptoms of Fluid Deficiency.—The clinical picture of burns is peculiarly deceptive, for a patient may appear to be in good condition even though disasterous derangements are imminent. Close clinical observation is of the greatest value in judging the adequacy of past treatment and planning for future treatment. Ravenous thirst, vomiting, restlessness, disorientation, mania, and increase in pulse rate, a decrease in blood pressure, collapsed veins, and oliguria are indications that therapy has failed to keep pace with fluid losses. Severely burned patients frequently have abdominal distention, nausea, and vomiting during the first 48 hours. The ingestion of fluids may aggravate vomiting, and this may cause an additional loss of electrolytes via the gastric juice. It is particularly important to interpret restlessness and disorientation as signals for the intensification of therapy and not as indications for the administration of narcotics. Changes in the pulse rate and blood pressure are not altogether reliable, since they may not occur until the patient's condition becomes critical. Although all of the signs and symptoms of deficiency are important, the most valuable single index in determining the adequacy of therapy is the rate of urinary output.

Specific Regimen of Therapy.—In general, burns that involve less than 20% of the body surface in adults require only a minimum of supportive therapy. Colloid solutions are not necessary, and fluid requirements are satisfactorily met by electrolyte solutions given orally and/or intravenously.

In more extensive burns, a 15 to 18 gage metal cannula or plastic tube, firmly secured in a vein, and an indwelling catheter in the bladder are absolutely essential for adequate therapy. Definitive local care must be postponed until the patient's general condition is stabilized. A rapidly applied emergency dressing, whose function is to protect the wound from contamination and to lessen pain, is all that is required. If pain or anxiety is severe, a small dose of a narcotic may be given. If possible, this should be given intravenously, since absorption from subcutaneous deposits is poor in the presence of impending or established circulatory collapse. Not infrequently, several large doses of narcotics are given subcutaneously without effecting pain relief; after reestablishment of good circulation by fluid therapy, simultaneous absorption of several doses of the drug may lead to serious central nervous system depression.

[11] Moyer, C. A.: Recent Advances in Chemical Supportive Therapy of Thermal Injury, Texas State J. Med. 45: 635, 1949.

Treatment requirements of an extensively burned patient must be selected for the individual patient against a background of the many variables that have been mentioned. Rules of thumb or formulas cannot be expected to predict accurately the requirements for all patients. Nevertheless, some yardstick for roughly planning fluid therapy during the first 48 hours is useful. For this purpose, a modification of the formula proposed by Evans has proved valuable.[12] The severely burned patient requires, in the first 24 hours, approximately 0.5 cc. of colloid solution and 1.5 cc. of a balanced electrolyte solution per 1/100 of the body surface burned per kilogram of body weight. In addition, adults require 1,000 to 2,000 cc. of either an electrolyte solution or water (figure).

Since the relationship between fluid requirements and percentage of burn is not linear throughout, fluid requirements of burns involving more than 50% of the body surface should be calculated as though only 50% had been burned. Unless this limitation is imposed on the use of the proposed formula, an excessive estimate of fluid requirements is made. In general, adults should not receive more than 10,000 cc. of fluids in the first 24 hours, regardless of the extent of the burn and the body weight. In the second 24 hour period, fluid requirements, qualitatively and quantitatively, are approximately one-half to three-quarters those of the first 24 hours.

Illustration of method of estimating fluid and electrolyte requirements for the first 48 hours after injury. Colloid and electrolyte needs are roughly determined by the extent of burn and the size of the patient. Details are given in the text.

If the patient can tolerate fluids given orally, a solution containing sodium bicarbonate and sodium chloride rather than water should be given. Administration of large amounts of water not containing electrolytes, by any route, carries with it the danger of dilution of the extracellular fluid. Dilution results in the shift of large quantities of water into the cells and is reflected clinically as the syndrome of "water intoxication." [11] The more serious the injury, the more jealously must the intake of electrolyte-free water be guarded. For very extensive, deep burns, we propose complete restriction of water intake in the first 24 hours, unless the infusion blood and a balanced electrolyte solution, in proper amounts, fails to sustain an adequate urine flow; only under this condition should free water be given, and then only in small amounts. In the second 24 hour period, less stringent water restriction is required, and thereafter water intake should be encouraged.

Whole blood is rarely required in partial thickness burns. When partial thickness injury extends over more than 30% of the body surface, some colloid in the form of a plasma expander is usually required. Whole blood is indicated in full thickness burns of more than 20% of the body surface. The larger the area of third degree burn and the deeper the burn, the more urgent is the need for blood transfusions. To what extent, if any, high hematocrit readings (hemoconcentration) contraindicate the use of whole blood in deep extensive burns has not been established. Serious red cell deficits and hemoconcentration frequently coexist because water and electrolytes are lost in greater quantity than red cells. Hemoconcentration causes increased blood viscosity.[13] Although a high blood viscosity has not been proved harmful, it appears likely that a high hematocrit does not serve any beneficial purpose. In the presence of a high hematocrit, whole blood should not be used unless large quantities of electrolyte solutions are given simultaneously. Whole blood may be administered when the hematocrit is at a level of 60 or below and decreasing, but it must be remembered that a high increasing hematocrit indicates primarily the need for electrolyte solutions. The need for whole blood is particularly striking in patients who have deep, extensive burns, who show signs of peripheral circulatory collapse, and who, at the same time, have normal or low hematocrit levels and fail to improve when electrolytes are given. If whole blood is not available, it is still possible to treat satisfactorily many deeply and extensively burned patients during the first 48 hours with the use of electrolytes and plasma expanders. The clinical course of these patients is generally less satisfactory than that of patients who are treated with whole blood initially.[14]

To keep pace with the fluid losses, approximately one-half of the fluid requirements of the first 24 hours should be given in the first eight hours, one-quarter in the subsequent eight hours, and one-quarter in the last eight hours. Clinical signs and symptoms and occasional hematocrit determinations influence the volume, composition, and rate of fluid administration. The urine volume should be measured every hour. An hourly output of 30 to 50 cc. of urine is satisfactory. A persistent urine flow of less than 30 cc. per hour is an indication for more rapid administration of fluids. A urine volume of more than 100 cc. per hour, on the other hand, indicates that the rate of fluid administration should be decreased. Although so-called "lower nephron nephrosis" (acute renal insufficiency) has been described after burns, we could not find a single instance of this complication in a series of 500 burn patients, 20 of whom died.[15] Oliguria and anuria in the first 48 hours after burning are nearly always caused by inadequate therapy and respond to intensification of therapy. It must be remembered, however, that in badly burned patients who have not had

treatment for many hours, the urine flow may not increase for many hours after institution of therapy. In these patients, fluid restriction in the mistaken belief that acute renal insufficiency exists results in an inexorably fatal outcome.

By the use of the regimen outlined, patients who are so severely burned that their chances for recovery are practically nil may survive for several days. If therapy is to be successful, advantage must be taken of the more or less predictable volume and rate of fluid losses. In this respect, the physician has a therapeutic opportunity that is rarely encountered in other diseases characterized by disturbed water and electrolyte distribution. If judicious treatment is instituted within a few hours after injury, the signs and symptoms of fluid derangement can frequently be prevented.

Fluid therapy after 48 hours is less well defined than it is in the initial period. According to our studies and experience, we must abandon the old concept that diuresis occurs after 48 hours as wound edema is resorbed and that, at the time of diuresis, fluid administration must be drastically reduced lest the circulation be overloaded. Dramatic diuresis was observed when burn patients were given fluids far in excess of the volumes now recommended, but when a regimen such as that proposed by Evans or our modification thereof, is employed the rapid mobilization of fluids is exceptional. If it occurs, it is a reflection of excessive fluid therapy prompted, in most instances, by overestimation of extent and depth of burn. A gradual increase in urinary output is more commonly seen. "Fluid redistribution" may be a better term to describe the changes that occur after 48 hours than "fluid resorption."

Therapy is guided almost exclusively by clinical signs and symptoms. Sufficient quantities of fluid should be given to assure good turgor of the unburned skin, fullness of veins, and a good tongue volume. Surprisingly large amounts of fluid may be required to accomplish this. After 48 hours, the urinary output becomes a totally unreliable sign of the adequacy of therapy, for serious water and salt deficits may develop in the presence of an adequate urine flow. The large quantities of nonprotein nitrogenous products released from the burned tissues (and possibly from other sources) demand excretion in the tubules of the kidney and act as osmotic diuretics.

Potassium excretion is high and subsides slowly over a period of weeks. Since severely burned patients tolerate only a very limited food intake during the first week, it is advisable to give potassium by mouth, beginning on the third or fourth day. Three grams of potassium chloride or, preferably, potassium phosphate in orange juice can be given by mouth three to four times a day until a normal diet is ingested.

Unfortunately, the factors that control fluid redistribution remain obscure. Until the fourth to the sixth postburn day, the serum levels of sodium, potassium, and chlorides usually remain within normal limits. At that time, the serum sodium level commonly decreases to 130 mEq. per liter or below, and we have observed that, concomitantly, the patient's clinical condition often deteriorates, as evidenced by high fever, tachycardia, tachypnea, and mental confusion. Low serum sodium levels are observed in metabolic adjustments to injuries other than burns and in a variety of medical diseases, including congestive heart failure, cirrhosis, and nephrosis. In burns, fluid redistribution sometimes proceeds in a manner reminiscent of these diseases. That a cause and effect relationship exists between the low serum sodium level and the patient's deteriorating clinical state is not necessarily true, but this possibility distinctly exists and must be studied further. Patients who are not too severely burned usually recover from this mysterious syndrome in several days; clinical improvement is not infrequently associated with diuresis of water and sodium. Those who are more seriously burned succumb despite the many heroic measures that have been employed in treatment.

SUMMARY

The complex nature of water and electrolyte shifts after burning is not yet fully understood. Although the volume and rate of fluid losses can be gaged with reasonable accuracy, the exact composition of fluid losses is as yet unknown and imposes serious handicaps in treatment. Fluid and electrolyte redistribution is a gradual process. It is characterized clinically by fever and tachycardia and occurs at approximately the time when the serum sodium level decreases. Burns involving 20% or less of the body surface can be managed satisfactorily with oral administration of electrolyte solutions, supplemented by small quantities of electrolytes, intravenously. In severe burns, a rough guide for therapy is provided by the formula in which 0.5 cc. of colloid and 1.5 cc. of electrolyte per 1/100 of body surface burn per kilogram of body weight and an additional 1,000 to 2,000 cc. of either an electrolyte solution or water are advocated. In the second 24 hour period, one-half to three-quarters of these amounts are usually required to satisfy fluid requirements. After 48 hours, clinical signs and symptoms govern fluid therapy. Because of the high losses of urinary potassium, beginning on the third day, administration of oral potassium solutions is advised.

ADDENDUM

Eight burn patients have died on our service since this paper was submitted for publication. Two of these patients had a clinical course and renal lesions compatible with a diagnosis of lower nephron nephrosis.

Suicide Rate at Record Low.—The suicide rate among industrial policyholders of the Metropolitan Life Insurance Company established an all-time low last year. The rate for 1952, namely 5.6 per 100,000 at ages 1 to 74 years, was 10% less than that in 1951; the previous low of 6.3 per 100,000 was recorded in 1945. . . . With the close of World War II, the suicide rate took an upward turn. The wartime motivations that usually lower the suicide rate were gone; many ex-servicemen experienced difficulties in readjusting to civilian life, and the tempo of industrial activity slackened. It was not possible to forecast then how long the suicide rate might continue upward or how high it would go. There was little comfort in looking back at the experience following World War I, because the upward trend in suicide which began in 1920 continued through the early 1930's. Fortunately, the pattern of the period after World War I has not been repeated in the experience since 1945. The fact that the suicide rate is now at a record low is a good index of the psychological and economic well-being of our people.—Suicide Rate at Record Low, *Statistical Bulletin*, Metropolitan Life Insurance Company, May, 1953.

PRECAUTIONS IN PEDIATRIC IMMUNIZATION PROCEDURES

Louis W. Sauer, M.D., Ph.D., Evanston, Ill.

During the past decade, the simultaneous immunization against diphtheria, tetanus, and pertussis has become quite well established on laboratory and clinical evidence. To retard the elimination of antigen (DTP) from the body and to enhance antitoxin and antibody development, various forms of aluminum have been used as adjuvant. Most private patients are now adequately protected by the customary primary series of three or four monthly doses, and subsequent recall (stimulating or booster) doses. Needless deaths due to pertussis are still occurring, however, in infants and children from families with low incomes and orphanages in congested cities and in rural areas. To reach these children, mass immunization clinics should function at well baby clinics, primary schools, and mobile units. The diverse difficulties encountered in the execution of these immunization procedures are problems due to earlier immunization, febrile reactions, alum cyst, postinoculation encephalopathy, paralytic poliomyelitis of the injected limb, and unfavorable results caused by the technique of mass immunizations. This paper deals with precautions in the solution of these problems.

EARLIER IMMUNIZATION

In 1925, Lovett and Hektoen [1] wrote: "Of all contagious diseases [whooping cough] is the most likely to affect the youngest members of the family; and herein . . . lies its chief danger. Even the tiny baby is not immune; for many cases occur . . . between the ages of one and three years." Kahn,[2] working with animals, made the fundamental discovery that "The capability to develop immunity is possessed to a considerably greater extent by the adult animal than by the young animal, and a given dose of antigen per kilogram of body weight that will produce marked immunity in the former animal may produce but mild immunity in the latter." I found, in 1933, that pertussis vaccine in an isotonic sodium chloride solution (in a total dosage of 80 billion Hemophilus pertussis, divided into three subcutaneous doses) conferred prolonged active immunity to infants after the age of 6 months but failed to protect when administered during the first months of life.[3] Pertussis occurred seven times more frequently in the latter group. Twelve years later, Sako, Treuting, Witt, and Nichamin [4] showed that alum precipitated pertussis vaccine protected most younger infants and prevented deaths due to pertussis when the disease was contracted later. Recently McComb and Trafton [5] reported that aluminum phosphate as adjuvant in DTP produced good protection and minimal systemic and local reactions.

The American Academy of Pediatrics [6] Committee on Immunization and Therapeutic Procedures recommends three monthly doses of slow absorbing (alum containing) DTP, starting at the age of 3 months, and the first recall dose one year after completion of the primary series. When begun before the third month of life, four monthly doses are advised. Some health departments, including those of Chicago and Evanston, and some physicians prefer to administer four monthly doses when the primary series is started before the 6th month. Three monthly doses are given when the primary series is started after the age of 6 months; their recall dose is not administered until several years after completion of the primary series.

PREVENTION OF FEBRILE REACTIONS AND ALUM CYSTS

Slow absorbing (alum-containing) DTP is preferred. It produces earlier, higher, and longer sustained immunity responses than did pertussis vaccine in isotonic sodium chloride solution, and, because of delayed absorption, febrile reactions are usually less frequent and milder. To reduce the incidence and severity, the mother should be instructed to keep the infant more quiet after injection and, if the infant is restless or feverish, to give an adequate dose or two of aspirin. Water should be offered repeatedly, a feeding or two reduced in volume, and excessive covers and sun avoided.

Deposition of alum along the needle tract produces regional fat necrosis, which terminates as an alum cyst or sterile abscess. When the individual dose was contained in a volume of 1 cc., alum cyst followed 2% of the injections. Since the concentration of the individual dose of slow absorbing DTP into a volume of 0.5 cc., and improvement of adjuvant and administration technique, the incidence of alum cyst has decreased to 0.12%.

In children under 3 years of age, alternate lateral gluteal areas (starting with the left proximal area) are preferred sites for the administration of alum-containing DTP antigens. The prone infant is held firmly, preferably by the mother, to lessen crying and squirming. Deviation of the needle from its original course seems to increase the likelihood of alum cyst formation. Termination of each deeply administered dose with an air bubble (0.1 cc.) is an added precaution. To prevent seepage, the needle should remain in place for a few seconds before it is quickly withdrawn. As a final precaution, the site should be promptly and gently massaged with sterile gauze. Subsequent doses (or penicillin) should not be administered at the site of a previous dose. After the 3rd

year, alternate upper arms may be used, starting with the left deltoid area. To lessen alum seepage, the needle is directed distally; after withdrawal, the area is covered with sterile gauze and three distally directed massage strokes are applied. Occasionally a deep, circumscribed alum nodule may be palpated for a month or longer. Adherence to these precautions almost completely eliminates alum cyst.

POSTINOCULATION ENCEPHALOPATHY

Byers and Moll[7] were the first to collect cases of encephalopathy following prophylactic pertussis vaccine injections. Toomey[8] augmented the number by sending a questionnaire to hundreds of pediatricians. The triad—fever, convulsions, and irreversible central nervous system changes—resembles that encountered not infrequently in cases of severe pertussis. In defense of pertussis vaccine it should be emphasized that this triad has been reported also after the administration of smallpox vaccine, diphtheria toxoid, typhoid vaccine, and influenza vaccine. Pertussis vaccine in isotonic sodium chloride solution was more frequently implicated than was slow absorbing DTP. The remainder of the vaccine in the vials caused no adverse symptoms when administered to other infants. Antigens of eight commercial biological laboratories were involved. Only once was a severe reaction reported after administration of a recall dose. Central nervous system instability was recorded in a high percentage of the family histories. Pediatricians frequently encounter convulsions in infants and young children at the onset of febrile infections such as exanthema subitum, tonsillitis, and pyelitis. Any child with a history of convulsions should not be given the injection. Should immunization seem desirable, however, fractional doses (0.2 to 0.3 cc.) may be tried at monthly intervals until the full total dosage has been administered. DTP administration should be deferred in premature and frail, nonthriving infants and in those with fever or a pustular infection of the skin or ears.

PARALYTIC POLIOMYELITIS OF INJECTED LIMB

In an editorial[9] "Poliomyelitis and Prophylactic Immunization" THE JOURNAL pointed out that paralysis of an injected limb was reported in several countries after the injection of various antigens. THE JOURNAL states: "Pending the results of further studies, the concept is prevalent in some quarters that children in whom paralytic poliomyelitis develops may have the pattern of their paralysis altered by injection of diphtheria and/or pertussis antigens during an epidemic. . . . Postponement of such immunizations for a few months, until the end of the epidemic, would appear particularly discreet . . . when these diseases are not unduly prevalent in the community at the same time as the poliomyelitis epidemic." Faber[10] collected reports of cases following the administration of diphtheria toxoid, penicillin, typhoid vaccine, cholera vaccine, and smallpox vaccination. It seems unlikely that these diverse medicaments might harbor poliomyelitis virus. One of the theories infers that these patients harbored latent poliomyelitis virus and that the trauma of the antigen induced the disease and localization of the paralysis. Another more likely theory assumes that inadequate sterilization of syringe or needle, or subsequent contamination of sterile syringe or needle with poliomyelitis virus, might have occurred from the physician's fingers or the patient's skin site or fingers. Faber stresses that syringes and needles used for injections should be sterilized by use of the autoclave or, if this is not possible, boiled for 20 minutes. His antiseptic for vial cap and skin site is 2% tincture of iodine.

The 1952 Report of the Committee on Immunization and Therapeutic Procedures of the American Academy of Pediatrics[6] cautions: "An outbreak of poliomyelitis in one's community is a signal for deferring elective immunization procedures in individuals over the age of six months. Primary immunization and/or recall injections obviously cease to be elective procedures when outbreaks of diphtheria, pertussis, typhoid or smallpox coexist with that of poliomyelitis." Physicians should heed these monitions.

STERILIZATION OF SYRINGES AND NEEDLES

Regardless of whether an injection is given in a physician's office, at home, or at mass immunization clinics, sterilization of syringes and needles in the hot oven should be the method of choice. It has been used exclusively at the Whooping Cough Research Laboratory for more than 25 years, during which time over 15,000 infants and children have been inoculated, with no instance of convulsion, postinoculation encephalopathy, or needle poliomyelitis reported. Needles and syringes remain sterile longer and are less readily contaminated than when sterilized by boiling.

Syringes (1 cc.) and needles (25 gage, ½ in.) rinsed in distilled water and dried are best sterilized in a dry, hot air oven maintained at 160 C (320 F) for one hour. A small, inexpensive gas-heated kitchen oven, an electric oven with an oven thermometer, or an electrically heated sterilizer with automatic temperature control is satisfactory. Supplies should be in the oven before the heat is turned on and should not be removed until the oven has cooled. Dried syringes (with attached needle) are placed in heavy-walled Pyrex tubes with gauze-covered cotton in the bottom and firm gauze-covered cotton plugs to facilitate handling. Extra needles, for use during office hours, are sterilized, two to four at a time, in smaller Pyrex tubes. Needles (20 gage), to be left in the vial to facilitate removal of each dose during mass immunizations, are sterilized singly in Pyrex tubes. When the DTP vial is empty, the needle is aseptically transferred to another vial after the cap has been cleansed with alcohol or other antiseptic. For use in mass immunization clinics, extra needles (point downward), cushioned on gauze, 40 to a Monel metal container, should remain sterile for weeks when sealed with adhesive tape. The same sterile syringes may be used without risk of contamination if needles are aseptically replaced with sterile forceps (tips under sterile towel or submerged in antiseptic when not in use) (see figure).

The British Medical Research Council[11] published "The Sterilization, Use and Care of Syringes" in 1945.

---

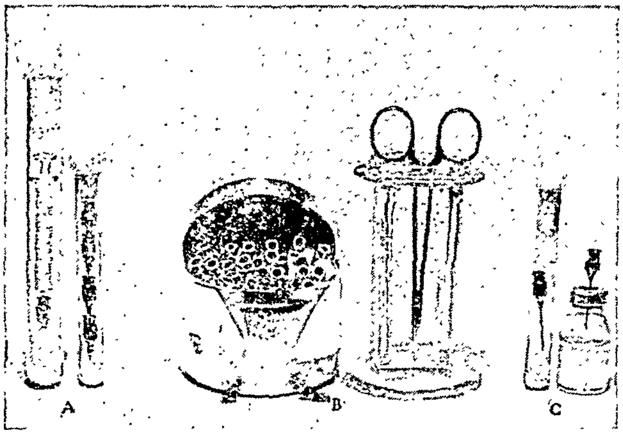
[8] Toomey, J. A.: Reaction to Pertussis Vaccine, J. A. M. A. **139**: 448-450 (Feb. 12) 1949.

[9] Poliomyelitis and Prophylactic Immunization, editorial, J. A. M. A. **144**: 240-241 (Sept. 16) 1950.

[10] Faber, H. K.: Postinoculation Poliomyelitis, editorial, Pediatrics **7**: 300-304 (Feb.) 1951.

This committee also recommends the hot air oven as the method of choice for sterilization of needles and syringes. They say: "Inflammations and infections following prophylactic inoculation and other types of injection are not uncommon. Abscesses and severe infections sometimes develop, and may occasionally be fatal. It is usually possible to trace a severe infection due to this cause to some technical fault which might have been avoided by the exercise of sufficient care. Any risk, however small, will produce accidents if it is repeated often enough. . . . Complete bacteriological sterility can be achieved only by sterilization in the autoclave or hot air oven. Boiling in water will destroy all pathogenic bacteria except those that produce resistant spores. . . . 'Sterile,' applied to a syringe and needle, implies that the syringe and needle have been through the process of sterilization in the autoclave or hot air oven. It is often loosely applied to a syringe that has been boiled. . . . Where many injections of the same fluid are given, the same syringe may be used for several consecutive subcutaneous or intramuscular—but not intravenous—injections, provided that a fresh needle is used for each patient. . . . Handle needles with sterile forceps only, syringes with dry, washed hands, taking care to touch only the outside of the barrel and the handle of the piston. Do not talk, cough or sneeze over a sterile syringe. Do not allow a sterile needle to touch any unsterilized surface or object before use. . . . Syringes and needles are placed in the oven while it is cold; the time of sterilization is not less than one hour after 160° C has been reached. The oven should be allowed to cool before the syringes and needles are removed. If syringes and needles are sterilized by autoclaving, a temperature of 120° C (15 to 20 lb. pressure) must be maintained for 20 minutes. . . . If an autoclave or hot air oven is not available, 'sterilization' by boiling in water is the method of choice, although boiling cannot be relied on to destroy all spores."



Syringes and needles used in DTP immunization. *A*, arranged for office use; *B*, in Monel metal containers for mass immunization use, and *C*, 20 gage needle left in vial cap during mass injections to expedite aspiration of 0.5 cc. doses of adjuvant-containing DTP.

If oven for sterilization or an autoclave is not available, needles and syringes should be boiled for not less than 10 minutes. If assembled when moist, it is conceivable that contamination might occur. Use of sterile forceps decreases this danger, especially when needles are replaced. Should poliomyelitis virus be introduced into a vial when a dose is aspirated and not be destroyed by the preservative before another dose is withdrawn, the virus might be transmitted to susceptible persons.

Sterilizing syringes and needles in an autoclave at 120 C is satisfactory but too time consuming as a routine procedure. It should be reserved for periodic sterilization of small bags of gauze squares and wrapped forceps used in needle exchange.

MASS IMMUNIZATION

Many infants in congested and rural areas are still victims of pertussis and die from its complications. Mass immunization clinics for the administration of slow absorbing DTP should be located at (1) well baby clinics, (2) primary schools, or (3) mobile units. Sessions should be held weekly, semimonthly, or monthly, depending on the number of infants to be injected. Linking pertussis and tetanus with long-established diphtheria immunization saves time for parent, nurse, and physician; it elicits minimal discomfort and hazard to the child. It is now customary to start the primary series at the age of 3 or 4 months, provided the child's health is satisfactory. Soon after an infant's birth, the maternity health nurse should inform the mother when to bring her infant, and the visiting nurse should remind her of the date for the initial dose. A mass immunization team of at least four facilitates antigen administration. When their work is coordinated, about 50 infants can be injected hourly without hazard to any child. The team keeps all records, teaches the mother how to expose the injection site and how she should hold her infant when the dose is administered, gives the card with dates for subsequent doses, and tells her what to do if high fever should occur. The team includes, preferably, a competent nurse who has complete charge of needles, syringes, and the antigen and a registered physician who cleanses each skin site with an individual sterile gauze square (2 by 2 in.), saturated with alcohol[12] before he administers the dose. Routinely, before the sterile syringes and needles are exposed, the nurse and physician wash their hands with soap (preferably under running water), dry on clean individually dispensed towels, and apply 70% alcohol to fingers. As an added precaution, their hands avoid unnecessary contact with any infant. The prone infant on the mother's lap, with only the proper gluteal area exposed is held firmly with her left hand at the knees and the right above the hips to prevent squirming. Each dose is delivered deeply (intramuscularly) and terminated with 0.1 cc. of air. After waiting for a few seconds, the needle is quickly withdrawn and the site gently massaged with the sterile gauze. Alternate lateral gluteal areas, starting with the left proximal are the sites of choice.

The Evanston Health Department established a municipal clinic for smallpox and diphtheria immunization in 1926. Pertussis immunization was added in 1932 and tetanus toxoid in 1944. Infants and preschool children of indigent families and those with low incomes are referred

---

[11] Medical Research Council: The Sterilization, Use and Care of Syringes, War Memorandum No. 15, London, His Majesty's Stationery Office, 1945.

[12] A few seconds should elapse for its antiseptic action. Early in 1952, following Faber's technique, 2% tincture of iodine was used; later, 1% in 70% alcohol was tried. Profuse lacrimation and frequent desquamation of the skin site made me resume use of 70% denatured ethyl alcohol.

to the clinic by infant welfare nurses and other agencies. After the parent signs the request slip, the infant is brought to the adjacent room by the mother and the dose is administered. When the series is completed, the parent is given an immunization certificate with the child's name, date of birth, parent's name and address, and date of completion of the injections. A master card is filed in the records of the health department clinic. The only recall dose of slow absorbing DTP (0.5 cc.) is administered before school attendance. During the decade prior to the establishment of the semimonthly immunization clinic (1922-1931) the total of reported cases of pertussis was 3,420 (16 deaths); during the last decade (1943-1952) the total has been 414 reported cases (no deaths). Private patients have been given injections by their physicians. Although the population of the city had increased by about 15%, the number of reported cases has decreased to 12% of that of the preimmunization decade. There has been no death due to diphtheria since 1938, to tetanus since 1940, and to pertussis since 1931.

Failure to confer immunity may be due to the use of impotent vaccine resulting from prolonged or repeated interruption in refrigeration (temperatures above 10 C, or 50 F); outdating; inadequate total basic dosage (when started as early as the 3rd month of life, some infants require four monthly doses of slow absorbing DTP); doses improperly spaced (less than one, or more than three months apart); delay or omission of routine recall or extra recall doses; poor technique (vial not adequately shaken, leaky syringe or needle, or seepage); exposure before immunity was attained; or wrong diagnosis (parapertussis, allergy, or influenza simulating pertussis).

SUMMARY

Diphtheria, tetanus, and pertussis morbidity and mortality warrant early primary mass immunizations with adjuvant containing DTP antigens and precautions against adverse reactions. Prolonged active immunity is attained by three monthly doses starting at 3 months and a recall (stimulating or booster) dose one year later, or four monthly doses starting at 3 months and a recall dose three years later. An extra recall dose (DTP or the specific antigen) should be given promptly after wounding, intimate exposure to diphtheria, or intimate exposure to pertussis. The hot air oven (160 C, or 320 F, for one hour) is the preferred method of sterilization for syringes and needles. Seventy per cent denatured ethyl alcohol on individual pieces of sterile gauze is adequate for sterilizing the vial cap and skin site. Deferment of prophylactic immunization procedures is advised during a poliomyelitis epidemic in the community.

CONVULSANT EFFECTS OF ISONIAZID

Richard H. Reilly, M.D., Keith F. Killam, M.S., Elizabeth H. Jenney, M.S., William H. Marshall, M.D.,
Chicago, Theodore Tausig, M.D., Manteno, Ill., Nathaniel S. Apter, M.D.
and
Carl C. Pfeiffer, M.D., Ph.D., Chicago

This report is the first collaborative effort of members of a university department of pharmacology, the staff of a state hospital, and the psychiatric division of another university faculty. Although we have outlined a coordinated research program, we do not assume that the degree of communication necessary for multidisciplinary research has yet been achieved. Data and information are being gathered and consolidated so that the common biological principles involved in our respective disciplines can eventually be more clearly formulated. In the meantime, we are utilizing common observations for emphasizing various perspectives on some similar problems. The pharmacologist is interested in studying the biochemical factors in epilepsy and identifying more effective chemotherapeutic agents for schizophrenic patients.[1] The psychiatrist makes the basic assumption that changes in the internal milieu will be reflected in behavioral alterations. Since the hydrazides alter cerebral cortical functions and produce electroencephalographic evidence of this alteration, this class of biochemical compounds seemed especially deserving of study. This research approach has been described elsewhere.[2] The psychiatrist is interested in the changes in behavior that may be obvious when data are collected prior to, during, and after the administration of hydrazides. Such comparisons may yield further insight into the schizophrenic reactions, the mechanisms by which convulsive experiences modify adaptations in chronic psychotic patients for longer or shorter periods, and the clinical events that signify reversibility or irreversibility of the schizophrenic reactions. This and current collaborative projects may be characterized briefly by stating that we are reciprocally exploiting each other's interests in basic biological and therapeutic problems.

PHARMACOLOGICAL BACKGROUND

The convulsions produced by many unsubstituted hydrazides, given in large amounts by any route, resemble grand mal epilepsy, in that major seizures appear

intermittently after a latent period of one to two hours.[1] Other convulsant drugs, administered intravenously, act immediately or, if given orally, produce continuous seizures of the clonic type.

Two known biochemical effects of hydrazides are carbonyl trapping and inactivation of amine oxidases.[3] Moreover, hydrazides lower the cerebral threshold for photic and auditory stimuli. After their administration, flickering light or repeated sounds produce spikes of high potential in the electroencephalogram and myoclonic movements of the extremities. If the stimulation is continued, a grand mal seizure may supervene. Semicarbazide, 40 mg. per kilogram of body weight given intravenously, produces grand mal seizures in man. When photic stimulation is used, the amount of semicarbazide required is reduced to 25 mg. per kilogram.[1b]

TABLE 1.—*Effect of Pretreatment with Semicarbazide on the Susceptibility of Mice to Pentylenetetrazole or Strychnine Toxicity**

0	101	0.79
25	80.3	....
50	41.5	0.80
75	28.0	0.73

* Ten mice were in each group.

The convulsant effects of hydrazides appear slowly but resemble the action of pentylenetetrazole (Metrazol) rather than that of strychnine. This was demonstrated by pretreating mice with subconvulsive doses of semicarbazide and then infusing pentylenetetrazole or strychnine intravenously. The threshold dose of strychnine is constant; however, the amount of pentylenetetrazole diminishes in direct proportion to the size of the pretreatment dose of semicarbazide (table 1). Direct application of semicarbazide to the cerebral cortex of the monkey provided additional evidence regarding the action of the hydrazides.[4] Within 20 minutes spiking appeared at the site of application, the inferior rolandic area. In 30 minutes the spiking spread to temporal and frontal areas. Generalized convulsive movements then ensued. Hydrazide-induced seizures can be controlled by depressant drugs or, in selected instances, by intravenously administered pyridoxine (vitamin B_6).[5] In one case a schizophrenic patient was ordinarily subject to convulsions after taking 4 gm. orally of semicarbazide plus photic stimulation. In this instance, 5 gm. was given orally and five hours later a control electroencephalogram was taken. Thereafter, the RT lead was switched out and all of the leads moved up, so that a recording could be made from the photoelectric cell on the forehead. A variation was seen in the base line of the photoelectric cell lead, owing to myoclonus of the neck muscles. When high potential spikes were obtained in all leads and a seizure was imminent, an intravenous injection of 225 mg. of pyridoxine hydrochloride was given over a 16 second period while photic stimulation was continued. The patient continued to have myoclonus for four to six minutes but did not have a seizure. In this patient spiking occurred earliest and remained latest in the frontal leads.

Isoniazid and iproniazid are inactivators of amine oxidases. Zeller reported that isoniazid is a potent inactivator of diamine oxidase but has little or no inhibiting effect on monamine oxidase. The reverse situation is, however, characteristic of iproniazid activity.[6] Animals given isoniazid die of convulsions with doses of 150 mg. per kilogram of body weight, while iproniazid-treated animals succumb in depression with doses of 750 mg. per kilogram. Therefore, it seems possible that isoniazid would produce convulsions in man but that iproniazid would not unless the isopropyl group was easily removed in the human body. Pyridoxine in the mouse can be used as a partial antidote for both isoniazid and iproniazid (table 2).

A review of the main side-effects of hydrazide therapy in tuberculous patients[7] discloses two types of clinical reactions: those referable to the autonomic nervous system, which are common, and those occurring as a consequence of stimulation of the central nervous system, which are rare (table 3). Convulsions have, however, been encountered. The tuberculous patient with epilepsy requires a higher maintenance dose of an anticonvulsant medicament during isoniazid therapy.

TABLE 2.—*Antidotal Effect of Pyridoxine on Iproniazid and Isoniazid Toxicity in Mice*

Group	Material	Dose, Mg. per Kilogram of Body Weight	No. of Mice Lived	No. of Mice Died	No. of Mice Total
1	Iproniazid intraperitoneally	800	5	23	28
	Iproniazid intraperitoneally and 400 mg. per kilogram of pyridoxine intravenously	800	15	16	31

	$\chi^2 = 8.29$ $p < 0.01$				

OBSERVATIONS ON PATIENTS

Four types of observations with isoniazid and iproniazid were undertaken in man. These were (*a*) the determination, by electroencephalographic technique, of the degree of sensitization to photic stimulation that isoniazid produces, (*b*) a comparison of isoniazid and iproniazid in a large number of patients to determine the degree of recruitment of facial muscles when patients are exposed to photic stimulation, (*c*) the effect of large doses of each of the drugs on the schizophrenic state, and (*d*) the determination of the convulsant dose of isoniazid in schizophrenic patients. Patients were observed closely before, during, and after the period of drug action. The use of flickering light to induce a seizure effectively reduced the required dose and allowed for the maximal medical assistance at the time of the seizure. During the period of susceptibility to convulsions, patients stayed in bed to prevent possible injury. All of the patients treated with iproniazid were kept on absolute bed rest during the period when postural hypotension developed. Laboratory examinations were performed frequently to detect signs of intoxication as early as possible. The behavioral status of each patient was observed closely to detect, if possible, any changes, minor or major. No concomitant illness existed in any of the chronic schizophrenic patients treated with the drugs.

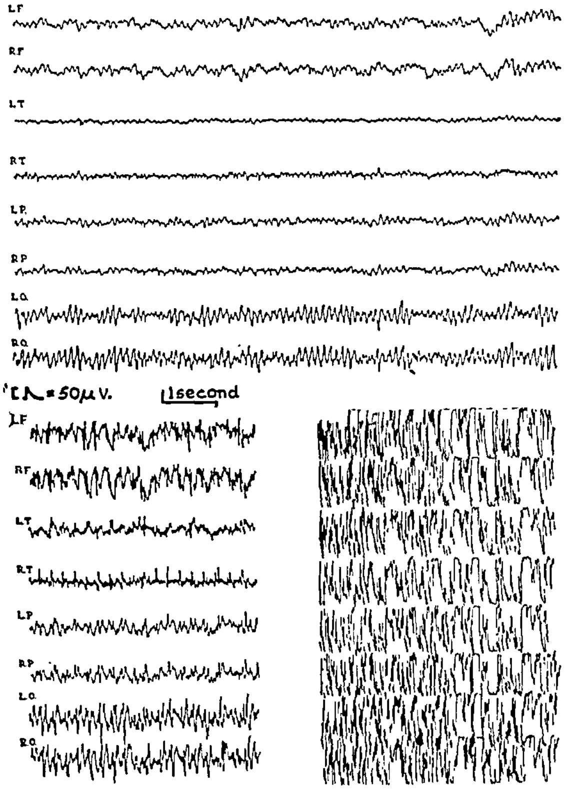
Electroencephalographic Studies.—Isoniazid greatly lowers the epileptogenic threshold for photic stimulation, so that the application of a flickering light (14 to 20 flashes per second) will produce a grand mal seizure. The convulsive response to photic stimulation is first manifested by an initial myoclonic twitching of the orbicularis oculi and supra palpebral muscles. This is followed by recruitment of the frontalis and jaw muscles and then generalized myoclonus, which terminates in tonic extension and loss of consciousness. The succession of movements resembles the pattern described by Gastaut, who used photic stimulation immediately after the intravenous administration of pentylenetetrazole, 7 mg. per kilogram of body weight.[8] The electroencephalogram at first shows an augmented alpha potential in the occipital leads and then spiking activity in the frontal leads. The figure shows the reaction of schizophrenic patient who was given 20 mg. per kilogram of isoniazid intramuscularly. Two hours later photic stimulation was started and continued for four minutes, after which a grand mal seizure occurred. The selected records are at one minute, two minutes, and four minutes. At one minute, the patient showed high alpha waves in the occipital leads. At two minutes, high potential spikes occurred in all leads but were more numerous in the occipital and frontal leads. The last record shows the grand mal seizure. By way of contrast, the electroencephalogram, after large intramuscular doses of iproniazid (25 to 40 mg. per kilogram), records no abnormalities over a period of three to four hours, nor do these large doses lower the threshold for photic stimulation. Large single doses of iproniazid are well tolerated. Signs of intoxication are, however, produced by daily doses of 15 mg. per kilogram.

Table 3.—*Untoward Effects Encountered in Tuberculous Patients*

	Daily Oral Dose	
Area Affected	Isoniazid, 4 Mg. per Kilogram of Body Weight	Iproniazid, 2 Mg. per Kilogram of Body Weight
Autonomic nervous system (common)	Dryness of mouth Constipation Delayed micturition	Dryness of mouth Constipation Delayed micturition Postural hypotension Syncope
Central nervous system (rare)	Vertigo Muscular twitching Hyper-reflexia Convulsions	Syncope Vertigo and tinnitis Convulsions when given with meperidine *Psychosis*
Miscellaneous (rare)	Nausea and vomiting	Nausea and vomiting Anemia Icterus

Recruitment After Photic Stimulation.—The phenomenon of recruitment of the facial muscles may be used to assay a lowered threshold for photic stimulation. In 31 patients of both sexes an oral dose of 15 mg. per kilogram of isoniazid induced recruitment to photic stimulation in 14 of the 31 patients two to four hours after the drug was given. When tested at the same time after an oral dose of iproniazid (15 mg. per kilogram), none of the 31 patients showed this recruitment. We, therefore, concluded that a hydrazide must be unsubstituted to produce convulsions.



Electroencephalogram of patient who received photic stimulation two hours after administration of isoniazid, 20 mg. per kilogram of body weight. A grand mal seizure occurred.

Use of Moderately Large Doses of Isoniazid and Iproniazid.—Isoniazid and iproniazid, in combination with photic stimulation, were administered to two groups of patients. Group 1 consisted of eight chronic schizophrenic patients with predominantly catatonic features and was designated for long-term therapeutic trial with moderately large doses. Patients of group 2, similarly composed, were observed to determine the convulsant dose of isoniazid. For both groups the drugs were given three times per week on alternate days. During a three month preliminary observation period there were no substantial changes in behavioral patterns. Group 1 was then submitted to two separate therapeutic trials. During the first trial, half of group 1 received isoniazid and half received iproniazid. The dosage was 15 mg. per kilogram of body weight for each drug. This was considered a subconvulsive dose. The drug was injected intramuscularly, and, about two hours later, the patients were photically stimulated (14 to 20 flashes per second) for five minutes. Blood pressure and pulse readings were taken frequently on treatment days (table 4). Iproniazid, after 9 to 10 treatments over a three week period, produced postural hypotension in all four patients and was, therefore, discontinued. The hemoglobin decreased to 60% of normal in one patient. After a two week rest period, all of the eight patients in group 1 were given isoniazid for the second trial. The patients who had been taking iproniazid received 15 mg. per kilogram of isoniazid. Those who had been taking isoniazid in the first trial had an increase in dosage to 25 mg. per kilogram intramuscularly (table 4). These large single intramuscular doses of isoniazid were without toxic effect and consistently produced a convulsion in only one patient. This seizure occurred with photic stimulation.

* Photic stimulation was 14 to 24 flashes per second applied hourly. *O indicates no seizure occurred in spite of photic stimulation.* PS indicates a seizure was induced by photic stimulation. T indicates that tachycardia with a pulse rate of over 130 per minute occurred. S indicates that a spontaneous seizure occurred. The figures in parentheses show the number of trials with the same designated dose in which the same result was obtained.

† Seizure accompanied by apnea of moderate duration.

Determination of the Convulsant Dose of Isoniazid.—The nine patients in group 2 were given steadily increasing intramuscular doses of isoniazid in increments of 5 mg. per kilogram, to determine the dosage at which convulsions could be induced with photic stimulation. This group was composed of nine chronic schizophrenic patients of various subtypes. The dosage schedule was arranged so that one male patient, L. K., was given 5 mg.

per kilogram more than the other five patients on all treatment days until a convulsive dose of isoniazid was ascertained (table 5).

In doses ranging from 20 to 45 mg. per kilogram given intramuscularly, 30 out of 62 trials resulted in no seizure and 22 resulted in a lowered threshold for photic stimulation, so that a generalized convulsion occurred. Eight trials produced tachycardia above 130 beats per minute; in these cases photic stimulation was not attempted and pyridoxine was given as an antidote. Spontaneous seizures occurred twice in one patient (B. B.) after doses of 35 and 40 mg. per kilogram, respectively. The only suggestion of a serious reaction was moderately prolonged apnea in one woman after a photic-stimulation-induced seizure. Doses as large as 40 mg. per kilogram were not reliably convulsant, since we have 4 failures at this dosage and 10 failures at 35 mg. per kilogram. Although these doses were given three times a week with a one day rest period in between, we had the impression that these patients were showing some degree of tolerance to the convulsive dose rather than an increase in sensitivity. All of the patients showed some degree of improvement in their mental state, but the improvement was not dramatic and was quite comparable to the degree of improvement that might be expected from equivalent electroconvulsive therapy.

COMMENT

In addition to a general intolerance to autonomic agents, possibly explained by an inhibitory effect on amine oxidases, the isoniazid-treated patient may have a central nervous system that is sensitized to auditory and visual stimuli. Thus, patients on high dosages of isoniazid should be warned and protected from flickering lights and repetitive noises. All patients should be carefully questioned regarding epilepsy, seizures, or convulsions in childhood when isoniazid therapy is contemplated. Since isoniazid is excreted in the urine, poor kidney function may also cause excessive intoxication.

If convulsions occur, 100 to 120 mg. of phenobarbital should be given slowly intravenously. Dienemann [9] reports that in a 50-year-old male tuberculous patient who was taking 6 mg. per kilogram of body weight of isoniazid daily, convulsive seizures developed 10 to 15 minutes after an injection of Irgapyrin (combination of phenylbutazone and aminopyrine). Phenobarbital (dose?) was given intramuscularly, and shortly thereafter respiration stopped. Analeptics and artificial respiration were ineffective. Thereafter, Simon [9] showed in the mouse that the convulsive effect of aminopyrine is enhanced by pretreatment with isoniazid. The possible convulsion enhancing effect of phenylbutazone (Butazolidin) was not studied.

Pyridoxine is completely effective in preventing grand mal convulsions in man and animals when simple hydrazides such as the semicarbazides are the convulsant agents.[10] This antagonism of pyridoxine against isoniazid can also be demonstrated reliably in animals; however, the antagonism is not complete, and, therefore, sodium phenobarbital should be the anticonvulsant of choice if convulsions occur in patients. With the usual doses of isoniazid, the patient who has convulsions probably has unsuspected epilepsy. Therefore, the greatest benefit might be obtained with depressant anticonvulsant medication such as phenobarbital rather than pyridoxine. Diphenylhydantoin is ineffective in the experimental animal and, therefore, is not indicated in these convulsions, nor should it be relied on to protect the epileptic tuberculous patient when isoniazid therapy is used. In the tuberculous patient, the use of pyridoxine as an antidote to isoniazid toxicity may temporarily negate the chemotherapeutic effect if these new agents inhibit the bacterial enzyme systems in which pyridoxine is involved; however, 200 to 400 mg. of pyridoxine can be given intravenously if continuous convulsions are uncontrolled by phenobarbital.

Isoniazid has been well tolerated intramuscularly by schizophrenic patients in single doses as high as 40 mg. per kilogram. These high doses should reassure phthisiologists of the safety of this new drug. This knowledge may be useful to those who give single high doses of either isoniazid or iproniazid to prevent bronchial infection at the time of the operation. The patients used in this study had normal kidney function and no epileptic tendencies—two facts that must be known before giving large single doses; however, the present dose of 4 mg. per kilogram a day of isoniazid has been determined to be moderately safe in all patients, and, therefore, the nonepileptic patient with good kidney function could probably tolerate safely 10 to 12 mg. per kilogram a day in divided doses and higher doses if phenobarbital is given concomitantly. These high doses should be chemotherapeutically more effective in the treatment of tuberculosis.

SUMMARY

Hydrazides lower the threshold for photic stimulation in both animals and man. Isoniazid alone or combined with photic stimulation may result in a grand mal seizure when large single intramuscular doses are given. The effective convulsant dosage of isoniazid varies with the person. The extremes in this study were from 22 mg. to 35 mg. per kilogram of body weight. Isoniazid caused spontaneous seizures in one patient with intramuscular doses of 35 and 40 mg. per kilogram. No dosage level of isoniazid up to 45 mg. per kilogram would consistently produce convulsions. A tachycardia of 130 or more occurred in a significant number of patients on high doses. These findings make isoniazid undesirable as a convulsant agent for shock therapy. Iproniazid in a dosage of 15 mg. per kilogram three times a week produced severe postural hypotension within three weeks in all patients, whereas single large doses were well tolerated. Iproniazid does not lower the threshold for photic stimulation and is, therefore, probably not directly convulsant in man. The slight change in mental status of some of the schizophrenic patients during hydrazide therapy was not remarkable.

DIABETES IN A NEW ENGLAND TOWN

REPORT OF FOUR YEAR PROGRESS STUDY OF THE OXFORD, MASS., DIABETES SURVEY OF 1946-1947

Hugh L. C. Wilkerson, M.D., U.S.P.H.S.
and
Leo P. Krall, M.D., Boston

The state of 70 diabetics after a lapse of time and the challenge of the premise "once a diabetic, always a diabetic" prompted a return to the town of Oxford, Mass., to study those persons previously identified as having diabetes in a community survey there. The results of the original survey had been interpreted, by some authorities, to mean that there were over one million unknown cases in this country. Of equal interest was a study of the behavior of incipient diabetes, or the so-called prediabetic state. In the winter of 1946-1947, a diabetes survey was made of 70.6% of the entire population of 4,983 persons in Oxford, Mass. The objective was to determine the prevalence of diabetes in an American community and to study methods for screening large groups for diabetes.[1] On the fourth anniversary of the Oxford survey, a progress study was begun in order to determine the status of the diabetics originally discovered and to investigate the interim development of diabetes in selected groups. It was thought this study would provide valuable information about the natural history and epidemiology of diabetes.

Certain facts about the original report should be recalled: 1. Postprandial blood and urine tests for sugar were done on all participants. 2. The age distribution of the population in Oxford, Mass., closely paralleled that of the United States in 1945. 3. Forty persons in the town were previously known to have diabetes, and 30 new cases were found. 4. Two per cent of the group tested had diabetes. 5. The most conservative estimate of prevalence for the town was 1.4%, based on 0.8% known and 0.6% previously unknown cases. This estimate assumed that no diabetes existed among the untested population. 6. If the number of unidentified cases among untested persons on the basis of the rate for persons tested is estimated and added, the prevalence of diabetes in Oxford becomes 1.7%.

The prevalence rate of 1.4 to 1.7% indicated in the original paper has been substantiated in several other surveys. From San Jose, Calif.,[2] a diabetes prevalence of about 1.6% in an industrial population was reported. In one of the most comprehensive studies to date, Kenny, Chute, and Best[3] did blood and urine tests on 81% of the 4,800 population of Newmarket, Ontario, Canada, and reported a prevalence of 1.2%. In general, the studies utilizing a combination of personal interview, history, and laboratory tests have proved that the earlier studies based on questionnaires have been far too conservative in their estimates of diabetes prevalence.[4]

The follow-up study in Oxford, Mass., was conducted in the winter of 1950-1951. The following groups from the original survey were included in the study, with a view to determining their present diabetic status: (1) the 30 cases of previously unknown diabetes that were discovered in the first survey, (2) the 40 cases of diabetes that were already known to physicians at the time of the first survey, (3) a blood sugar suspect group of 118 persons with borderline or relatively higher than normal blood sugar readings in the first survey, (4) a control group of 225 persons with average or normal blood sugar readings in the first survey, conforming in age and sex distribution to the blood sugar suspect group, and (5) a glycosuria suspect group of 17 persons repeatedly showing sugar in the urine with variable blood sugar levels that did not meet the criteria for the diagnosis of diabetes.

TABLE 1.—*Status of Seventy Diabetics from the Oxford, Mass., Survey on Follow-Up, 1950-1951*

Status on Follow-Up, 1950-1951	Total	Newly Discovered, 1946-1947	Known Prior to 1946-1947
Total	70	30	40
Living, diabetic	47	20	27
Living, diabetes questioned	7	2	5
Dead, diabetic	15	7	8
Dead, diabetes questioned	1	1	..

METHODS

For the diabetics studied, a short interim history was recorded, including information on changes relative to general health and diabetes. Venous blood specimens were taken one to two hours after a meal containing at least 50 gm. of carbohydrate. Blood sugar analyses were done by the standard Folin-Wu method, as they had been in the 1946-1947 survey.[5] The presence of urinary sugar was detected by the suitable diagnostic procedures (Clinitest and Galatest). In addition, when the diagnosis of diabetes was in question, a three hour 100 gm. oral glucose tolerance test was done. Limited follow-up studies had been done on the diabetic patients in 1948,

[5] Because of the increasing trend to true blood sugar determinations, as championed by Mosenthal and Barry (Criteria for and Interpretation of Normal Glucose Tolerance Tests, Ann. Int. Med. **33**: 1175 [Nov.] 1950), Haunz and Keranen (Clinical Interpretation of Blood Sugar Values: Study of Folin-Wu, Somogyi-Nelson and Wilkerson-Heftmann Blood Sugar Determinations in 100 Subjects, Proc. Am. Diabetes A. **10**: 200, 1950), and others, the Somogyi-Nelson blood sugar determination was also done on each blood specimen in order to confirm the Folin-Wu procedure. A comparison of different blood sugar methods is the subject of another paper.

and occasional reference will be made to these data where meaningful.

One of the newly discovered, or unknown, cases and five of the previously diagnosed, or known, cases had moved from the town, and the status of each of these six was determined by visit or correspondence. For the blood sugar suspect group, the control group, and the glycosuria suspect group, the same type of interim history was recorded and the same procedure of postprandial tests was done if possible, though occasionally blood sugar determinations were made with capillary instead of venous blood, according to the Folin-Malmros method. To establish the possibility of diabetes, if any patient in these groups had a postprandial venous blood sugar reading between 140 and 200 mg. per 100 cc. in the progress study, a standard three hour 100 gm. oral glucose tolerance test was done where possible.

* *Unless otherwise stated, highest postprandial blood sugar readings are shown, determined by venous Folin-Wu method: C = capillary blood, determined by Folin-Malmros; T = highest reading on glucose tolerance test, unless otherwise stated; and F = fasting blood sugar.*

For the sake of consistency in comparing results, the diagnostic standards of the original study were used—over 170 mg. per 100 cc. on venous blood (Folin-Wu) or over 200 mg. per 100 cc. on capillary blood (Folin-Malmros), confirmed by the analysis of a second specimen. In one case postprandial blood was not obtained and a confirmed fasting Folin-Wu test of over 130 mg. per 100 cc. was accepted as diagnostic. In the original study all patients with questionable or borderline cases had been given a standard oral glucose tolerance test, in which attention had been paid primarily to the height of the curve. In the current follow-up, however, attention was paid to both the height and duration of the curve. Occasionally a diagnosis was considered justifiable on the basis of a single very high postprandial blood sugar test when confirmed by the analysis of a second postprandial specimen.[6]

COURSE OF THE DISEASE IN THIRTY PREVIOUSLY UNKNOWN AND FORTY KNOWN DIABETICS

In the four year progress study the first problem was to determine the validity of the original classification of patients (table 1). Forty-seven of the total of 70 persons classified as diabetics in 1946-1947 were living in 1950-1951 and showed evidence of diabetes. Another seven now living would have questionable diagnoses on the basis of current laboratory data, if the past evidence of diabetes were not available. Therefore, they are designated in table 1 as diabetes questioned. Sixteen of the 70 have died, 15 of whom were considered diabetic and 1 of whom had hyperglycemia and glycosuria that might possibly have been related to gastrectomy one year prior to the 1946 survey, history of which was obtained subsequently. Deserving of special comment are the eight cases in which the original classification of diabetes may now be questioned (three newly discovered and five previously known; seven living and one dead).

[6] Diabetes Guide Book for the Physicians, New York, American Diabetes Association, Inc., 1950.

In most of the group of 30 who were newly diagnosed in 1946-1947 on the basis of laboratory findings and confirmation by their attending physicians (table 2), the classification of diabetes has been borne out in the progress study. For a summary of three exceptions, see cases 1, 7, and 12. In the original survey, the patient in case 1 had been considered to have borderline or very early diabetes, which should have been followed. His one hour venous blood sugar tolerance peak had been 190 mg. per 100 cc., with a drop to 128 after two hours. In 1948, he had a similar glucose tolerance curve with glycosuria, but in 1950-1951 he had a normal curve with glycosuria. He has never been overweight and did not develop any signs of frank diabetes in four years. His paternal grandmother died of diabetes. In case 7, the response to the original glucose tolerance studies in 1946 had been a one hour blood sugar peak of 260 mg. per 100 cc. plus glycosuria, with a decrease to 150 mg. per

[*] Highest postprandial blood sugar readings are shown, determined by venous Folin-Wu method. Those noted as C are capillary, determined by Folin-Malmros.

[†] NPH = modified protamine insulin.

[‡] PZI = protamine zinc insulin.

[§] R = regular insulin.

100 cc. in two hours, and a drop to 74 mg. per 100 cc. in three hours. Subsequent inquiries disclosed that some time prior to the original test, the patient had had a subtotal gastrectomy. These findings suggest the possibility of a "dumping syndrome," as described by Custer, Butt, and Waugh[7] and others. This patient died of coronary heart disease in 1948 at 53 years of age. In spite of the possibility that rapid intestinal absorption accounted for the diabetes picture, we believe he had a mild case of diabetes. In case 12, 20 lb. (9.1 kg.) of weight were lost in the four year interval. On the basis of laboratory tests alone, a classification of diabetes was not justified in 1948 or in 1950. Weight reduction, particularly in a person with mild diabetes, can result in the disappearance of symptoms and signs of the disease.

For each of the 40 cases in which diabetes had been diagnosed prior to 1946 (table 3), an attempt was made to confirm the patient's history of diabetes with his physician. In 5 of these 40 cases (37, 40, 43, 53, and 60) neither laboratory data in 1946-1947 nor progress data in 1950-1951 confirmed the original classification of diabetes, which had been made on the basis of medical history and confirmation of family physician. In three of the five cases, the original reported history of diabetes was of considerable duration, varying from 10 to 20 years.

It is interesting to note that the follow-up study revealed, through the search of death certificates, that at least three other diabetics, heretofore unknown to the investigators, had been under treatment in Oxford at the time of the original survey. These were clear-cut cases of diabetes, in which the patients had been given insulin and had diabetes listed on their death records. One other known diabetic came to our attention only recently, when he had a leg amputated. These four persons had not been listed as known diabetics in the original survey.

On the basis of the follow-up study in Oxford, on the whole, the original classification of diabetics seems justified. In the eight cases cited, the diagnosis of diabetes may currently be questioned on the basis of laboratory tests; however, we agree with a group of medical consultants who emphasize that at one time these eight have been diagnosed as diabetic by their family physicians and those now living might well be mild diabetics in remission.

DEATHS AMONG DIABETICS

Of the 70 diabetics listed in the original survey in 1946-1947, at least 62 were still considered to be diabetics in 1950-1951 (table 1). In the four year interval, 15 of this group had died, leaving 47 of the original group alive. Seven of the 15 deaths occurred among the diabetics newly discovered in 1946-1947, and 8 among the group discovered previously. According to age at time of death, mortality had occurred as follows: Of the 15 persons from age 55 to 64, 5 had died; of 11 aged 65 to 74, 4 had died; of 11 attaining age 75 or over, 6 had died. An estimated annual death rate for the group aged 55 to 74 would be 86.5 deaths per 1,000 per year, which is considerably higher than the general mortality experience for the state of Massachusetts, which was 29.7 for that age group. The average age at death for the total group of diabetics was 72: 76 for the group discovered in the original survey, and 68 for those previously known.

As to the cause of death, two died at about age 64 with diabetes and kidney disease, one of them in diabetic acidosis. Five deaths were due to cancer and two with associated kidney disease. Three deaths were attributed to coronary heart disease and two to other forms of heart disease. One death was due to cerebrovascular accident. Two deaths occurred outside the area, and the cause has not been obtained. Diabetes was listed on only 4 of the 13 death certificates available for study. Some form of arteriosclerosis was named on six certificates.

CHARACTERISTICS OF GROUP LIVING WITH DIABETES DURING FOUR YEAR PERIOD

It was possible to study the 47 diabetics classified in the 1946-1947 survey who were living in or near Oxford in 1950-1951. As can be seen from table 4, 27 of the group, or about 57%, were aged 45 to 64 years. Several factors were recorded on the interim history or under laboratory data in order to indicate in some degree the control maintained. A history was taken of any serious illnesses or complications of diabetes, such as acidosis, gangrene, blindness, cataract, glomerulosclerosis, or gallbladder disease. Physical examinations were not done, and this limited the completeness of the data. Details of the findings for individual cases are presented in tables 2 and 3.

TABLE 4.—*Age Distribution in 1950 of Forty-Seven Diabetics from Original Survey*

Age Group	Total	Discovered During Survey	Known Prior to Survey
Total	47	20	27
20 to 44	8	3	5
45 to 64	27	14	13
65 to 74	6	2	4
75 and over	6	1	5

Methods of Control.—Information was obtained from the 20 living patients who had been newly discovered in 1946-1947 as to whether they were under treatment with insulin and/or diet. Five of the group reported no attempt at control by either diet or insulin. In all of these the laboratory results indicated blood sugar above 200 mg. per 100 cc. Glycosuria was present in all but one. Twelve reported some limited adherence to diet without insulin, although the diet history was not obtainable in detail. Only two of the group were given insulin therapy along with diet therapy. Reliable information could not be obtained from one person, but it was thought that no effort was being made to maintain control. Among the 27 old cases remaining from the group diagnosed prior to 1946, some degree of control was reported by more patients than in the newly discovered group. All, in fact, reported some type of control. Nine reported dietary control only; 2 reported they were given insulin without any particular dietary control; and 14 had both diet and insulin. In two cases reliable information was not available.

Glycosuria and Blood Sugar Results.—Glycosuria was a common finding among the diabetics in the progress study. Thirty-three out of the 40 tested (or 83%) had some degree of glycosuria. Glycosuria was equally common among both the previously discovered and the newly discovered group. If it had been practical to collect 24 hour urine specimens, it is thought that glycosuria would have been present in every case. There were available for study 35 comparable postprandial blood sugar determinations for 1946-1947 and 1950-1951 in the group of 47 diabetics studied. There was interest in the level of blood sugar maintained and any significant changes since the original survey. The correlation of 1950-1951 blood sugar levels to those of the original study is shown in table 5. In 1946-1947, 9 had blood sugar readings above 250 mg. per 100 cc.; in 1950-1951, 16 had blood sugar readings this high. Since 1946, 13 of the diabetics studied have shown a marked increase in blood sugar readings, 14 have the same range of blood sugar, and 8 have shown a decrease. Those showing marked increases in blood sugar readings were almost all among the previously known group, and the newly discovered group have generally the same blood sugar distribution as in the original study.

[7] Custer, M. D., Jr.; Butt, H. R., and Waugh, J. M.: So-Called "Dumping Syndrome" After Subtotal Gastrectomy: Clinical Study, Ann. Surg. **123**: 410 (March) 1946.

Serious Illness.—A history was recorded regarding serious illness and hospitalization occurring between the original survey and the follow-up period. Only five, 25%, of the 20 in the newly discovered group reported serious illness in the interim period. These include one case each reporting kidney disease, heart disease, failing vision, arthritis, and debility of old age. From the data collected, the relation of these conditions to diabetes cannot be postulated. It is significant that 15, 75%, of these newly discovered patients, reported no serious illness. The history of serious illness was much commoner among the 27 in the previously known group. Fourteen, or about 52%, of them reported some type of serious illness. Two reported amputations due to gangrene; one was blind as a result of diabetes of 28 years' duration; three others reported failing vision, and one a diabetic cataract as well as kidney disease. One young woman with moderately severe diabetes under treatment with both insulin and diet reported two spontaneous abortions. Other illnesses reported are listed in table 3. Only 10, or about 37%, of the diabetics in the previously known group reported no serious illness. In three cases, or 11%, the history of illness was incomplete.

TABLE 5.—*Venous Folin-Wu Postprandial Blood Sugar Readings of Thirty-Five Diabetics*

	Blood Sugar in Mg. per 100 Cc., 1946-1947	Blood Sugar in Mg. per 100 Cc., 1950-1951				
		Below 170	170 to 199	200 to 219	250 to 299	300 and Over
Total	35	6	6	7	5	11
Below 170	5	3	..	..	1	1
170-199	10	1	5	..	2	2
200-219	11	2	1	4	..	4
250-299	6	..	..	2	1	3
300 and above	3	..	..	1	1	1

The information on these cases is not complete enough to evaluate precisely their physical condition and to relate these findings to the degree of control of their diabetes; however, a general description of the health problem created by diabetes in a small community can be drawn from the study. The diabetics are chiefly a middle-age group, with some in the older age brackets. Their life expectancy is less than that of the average person. Judging from laboratory findings, glycosuria is quite common and about half of the diabetics have markedly elevated blood sugar readings, indicating a lack of control. The commonest method of control was diet, with more than one-third of the patients being given insulin too. Many of these patients, particularly those with diabetes of long duration, have serious illnesses, some of which are undoubtedly related to diabetes. This is acknowledged to be only a part of the picture of diabetes morbidity and its sequelae as they affect the community.

BLOOD SUGAR SUSPECT GROUP AND CONTROL GROUP

In the original survey the screening level, i.e., the level above which blood sugar readings were considered suspicious of diabetes, was 160 mg. per 100 cc. by venous Folin-Wu method, or 190 mg. per 100 cc. by capillary Folin-Malmros method. About 3% of the total number of persons examined from one to one and one-half hours postprandially fell above this point. If we go a little lower down the blood sugar scale to 140 mg. per 100 cc. with venous or 170 mg. per 100 cc. with capillary blood, about 8% of the group will be screened out. In this borderline group with blood sugar above 140 mg. in venous or 170 mg. *in capillary blood per 100 cc., but not* satisfying the diagnostic criteria, we suspected that more diabetics would have developed in the four year interim period than among those with lower blood sugar levels. The answer to this problem might give some clue to the prediabetic state, or at least indicate a group that should be reexamined periodically. In this report this group is arbitrarily called the blood sugar suspect group. In addition to the persons classified as diabetics in the original survey, therefore, the persons who had had borderline or relatively higher than normal blood sugar levels in 1946-1947, but who were not diagnosed as diabetic, were studied.

There were 161 persons who had had blood sugar readings above 140 mg. per 100 cc. by venous Folin-Wu or above 170 mg. per 100 cc. by capillary Folin-Malmros, but had not met the diagnostic criteria of the survey. About a third of these had been reexamined in 1946-1947, as they had had readings above the screening level but had been considered nondiabetic by subsequent tests. Of the original 161 persons, 43 were inaccessible in 1950-1951, 18 having died and most of the remainder having moved away. The remaining 118 were examined by means of blood and urine sugar tests. The routine procedure has been described under methods.

As a control group with which to compare the blood sugar suspect group, a sample of 294 was selected from the 3,277 persons in the original survey with venous blood sugar readings below 140 mg. per 100 cc. or capillary blood sugar readings below 170 mg. per 100 cc. This sample was selected so as to conform with the age and sex distribution of the suspect group. In the follow-up, we were able to test 225 of these for diabetes, since 24 had died and the remainder had moved or were not available. The age distribution of the two groups is quite close, although not exactly matched after the loss of persons who died or moved. The control group has 8% more persons 45 to 54 years of age and 4% fewer persons 35 to 44 years old. These differences render the conclusions conservative, since it is generally conceded that diabetes becomes more recognizable in persons over 45. Both the blood sugar suspect group and the control group have an equal distribution of men and women.

In the blood sugar suspect group as well as in the control group, about 83% of those selected to be studied were given laboratory tests. As a result of testing 118 persons with relatively high blood sugar readings, 17 diabetics were discovered, or 14.4%. In the control group of 225 persons, 4 diabetics were found, or 1.8% (table 6). The difference between the percentage of diabetics in the blood sugar suspect group and the percentage of diabetics in the control group is significant, since this difference might occur by chance alone less than once in 1,000 times.

Table 6.—*Results of Diabetes Examinations, by Age, in a Blood Sugar Suspect Group and a Control Group**

	Suspect Group			Control Group		
	No. of Persons	Diabetics		No. of Persons	Diabetics	
Age in 1950	Examined	No.	%	Examined	No.	%
All ages	118	17	14.4	225	4	1.8
Under 35	35	..	....	65	..	...
35-44	20	3	15.0	29	..	...
45-54	18	5	27.8	52	..	...
55-64	23	5	21.7	39	3	7.7
65 and over	22	4	18.2	40	1	2.5

* The suspect group includes persons who had in the original survey blood sugar readings above 140 mg. per 100 cc. venous or 170 mg. per 100 cc. capillary. In the control group the readings in original survey were below these values.

Particularly notable were three young persons, two men and one woman, aged 35, 36, and 35, respectively, who had had readings around 140 mg. per 100 cc. in 1946-1947 and who were now diabetics. The percentage of diabetics among persons over age 35 was 20.5 in the suspect group, as contrasted with 2.5 in the control group. The proportions of diabetics were higher in the suspect group than in the control group for both men and women.

Several different blood sugar levels from the 1946-1947 survey were studied in relation to later development of diabetes. Of the 161 with suspicious blood sugar results, about 80% had had levels in the first test in 1946-1947 below the diagnostic level (170 mg. per 100 cc. Folin-Wu or 200 mg. per 100 cc. Folin-Malmros). The remainder had shown hyperglycemia above these diagnostic levels that was not demonstrated again on tests repeated within a few days after the first test. Of the original 161 cases with suspicious blood sugar results, 36 had had capillary blood analysis. On follow-up of 25 of these, none proved to be diabetic; however, 72% of these were children under 20 years of age in whom diabetes is relatively uncommon. Of 125 persons with original suspicious venous determinations, 88 were successfully followed. When these persons are grouped on the basis of their original blood sugar readings (in 1946-1947), the following comparison can be made:

1946-1947 Venous Blood Sugar Reading (Mg. per 100 Cc.)	No. Examined	Diabetics in 1950-1951	
		No.	%
140-170	75	13	17.3
170-200	13	4	30.8
Total	88	17	19.3

It can be seen that the larger number of those studied (75) and most diabetics found (13) occurred in those persons in the suspect group who at no time reached the diagnostic level of 170 mg. per 100 cc. The percentage becoming diabetic was higher, as might be expected, among those few persons with definite hyperglycemia (170 to 200 mg. per 100 cc.) on first test alone, which was not confirmed on recheck. These findings in the suspect group are consistent with a recent statement of Lukens[8] that he has become suspicious of any blood sugar value above 140 after meals, although a single report at such a level does not warrant the diagnosis of diabetes.

GLYCOSURIA STUDY GROUP

In the original report[1] the following statement was made: "Tentatively 17 subjects were considered as having unclassified glycosuria, because of persisting glycosuria in the absence of hyperglycemia. It is believed that 7 of these persons may become diabetic because of widely fluctuating blood sugar levels." At that time these cases were not thought to fit the so-called renal glycosuria classification because their laboratory findings were too variable. In the follow-up study of the group with unclassified glycosuria, four persons were found to be diabetic (three of these had been among the suspicious seven in 1946-1947). Six continued to show glycosuria without accompanying hyperglycemia, five showed no laboratory signs of diabetes, and two died. In the original survey, 9 of the 17 with persistent glycosuria had blood sugar readings above 140 mg. per 100 cc. venous and were therefore included with the blood sugar suspect group. Of these nine persons, three had become diabetic in 1950 and two continued to show glycosuria. Of the 17 with persistent glycosuria, 8 had had blood sugar readings below 140 mg. per 100 cc. on original survey. One of these persons had become diabetic in 1950, while four continued to show glycosuria.

CRITERIA OF DIAGNOSIS IN FOLLOW-UP STUDY

As has been noted, in order to obtain comparable results the criteria used in the follow-up study were the same as those used in the original survey. However, glucose tolerance tests (table 7) for 13 of the 22 diabetics discovered since 1946-1947 have been carefully studied in relation to current criteria for diabetes. According to the criteria of the American Diabetes Association,[6] diabetes is present when the blood sugar is above the following levels (venous Folin-Wu): 200 mg. per 100 cc. after eating and 130 fasting. They emphasize that the fasting blood sugar may be normal in early diabetes.

In the series of 13, all except 4 patients had above 200 mg. per 100 cc. blood sugar levels at one hour. Of the four exceptions three had about 190 mg. per 100 cc. at that point and one had 174 mg. per 100 cc.; however, at the fasting reading, the majority of the diabetics, 9 out of 13, had readings well below 130 mg. per 100 cc. At the three hour reading, 5 of the 13 were below 130 mg. per 100 cc.

The elevated two hour reading on glucose tolerance test has been considered by many observers as the key figure in diagnosis of diabetes. Recently Moyer[9] has recommended 150 mg. per 100 cc. at two hours as indicative of diabetes, and this criterion appears reasonable. All of the diabetics in this series were above 150 mg. per 100 cc. at two hours with one exception, who was only slightly below. All of the persons classified as diabetic demonstrated glycosuria repeatedly, the one exception being a woman of 80 years. Comparison of the glucose tolerance findings in this series with criteria recommended by the American Diabetes Association and other authorities shows close agreement. The classification of diabetes in these cases, it is believed, would be generally accepted.

* Diagnosed by private physician between 1946 and 1950. In all cases starred, except 77, insulin was given. All blood sugar determinations are venous Folin-Wu.

COMMENT

Of concern and importance in the detection, diagnosis, and management of diabetes are those patients who have been shunted aside or not thoroughly followed because they have "a little sugar in the urine" or blood sugar "a little higher than normal." Our findings tend to indicate that these are the future diabetics. Whatever preventive measures are available to the medical armamentarium could be best focused on these cases of near diabetes. It should be emphasized that case finding can never be an end in itself. It is effective only when combined with follow-up, patient education, and attainment of adequate treatment through the earnest teamwork of the physician and his patient. "From the preventive aspect, of primary importance . . . is the actual determination of whether or not early treatment will lead to a lessening of the severity of the disease, increased ease of control, and facilitate the prevention of complications."[10]

There is a need to determine a widely acceptable clinical definition of diabetes control. More definitive study is necessary to determine the prognosis in relation to the various degrees of such control. We recognize the great importance of attempting to relate the control of diabetes in the individual person and in the community to the control of either mortality or the development of complications, but we also realize that the amount and scope of our data are inadequate up to this time. Our current efforts in diabetes epidemiological studies are directed, therefore, toward the procuring of sufficient data to bridge some of the gaps in our knowledge of detection and control factors in diabetes.

SUMMARY

A four year diabetes follow-up study was made in Oxford, Mass., in 1950-1951 of the following groups selected from those persons tested for diabetes in the original 1946-1947 survey: 70 diabetics identified in 1946-1947; a blood sugar suspect group of 118 with

[10] Commission on Chronic Illness, *Proceedings of the Conference on the Preventive Aspects of Chronic Disease*, March 12-14, 1951, Raleigh, N. C., Health Publications Institute, Inc., 1952, p. 216.

borderline or relatively higher than normal blood sugar readings in the original survey; a control group of 225 with average or normal blood sugar readings in the original survey; and a suspect group of 17 with repeated glycosuria. The purposes of the study were to investigate the diabetic status and general health of the diabetics seen in the original survey, verify the cases of diabetes first observed, and investigate the incidence of diabetes in the interim period among a suspect group selected on the basis of relatively high blood sugar readings.

The method of the study was to obtain postprandial blood and urine sugar analyses, and glucose tolerance tests when necessary. Also an interim history of diabetes and general health was recorded. In 62 of the 70 diabetics observed in the original survey, the classification of diabetes was justified on follow-up. In seven of the other eight cases currently failing to meet criteria for diabetes, there exists the possibility of remission of mild diabetes, but they are subject to question. In one patient, now dead, we believe mild diabetes was present, but the possibility exists of a "dumping syndrome." There were found to be at least four known diabetics living in Oxford at the time of the original survey who had not been listed in the first study. Of the original group of 70 diabetics, 16 have died. The death rate for the age group 55 to 74 years is higher than general mortality experience for that group.

For the 47 in the original group of diabetics who were still living, a study was made of the method of control of diabetes, glycosuria and blood sugar results, and serious illness or diabetic complications. These findings emphasize the original conclusion that there is a need in the community for improved control in the diabetics. The blood sugar suspect group studied was comprised of 118 persons with blood sugar readings in the original survey above 140 mg. per 100 cc. (venous) or 170 (capillary); the control group was made up of 225 persons with original blood sugar readings below these values. In the blood sugar suspect group, 17 diabetics were discovered, or 14.4%; in the control group, 4 diabetics were discovered, or 1.8%. The high incidence of diabetes in the blood sugar suspect group suggests that persons with relatively high but not diagnostic blood sugar levels should be periodically followed. The findings indicate that it is likelier that diabetes develops in such persons than in persons with average or normal blood sugars. Among a group of 17 persons with unclassified glycosuria in the original survey, 4 have become diabetic in the four year interval. (Of these diabetics, three were included also in the blood sugar suspect group.) This suggests that the allegedly harmless glycosurias may often hide incipient diabetes.

At the time of the four year follow-up study, 69 living diabetics in Oxford were known to the investigators. The general picture is that most of those who had diabetes still have the disease, which has progressed since the 1947 study. Some of the severest degenerative sequelae appeared to be present in the patients with the poorest degree of control, although this is not definitely proved at this time. More detailed follow-up studies continue on all groups described.

CLINICAL NOTES

ACUTE PSYCHOSIS AS A COMPLICATION OF HYDRALAZINE THERAPY IN ESSENTIAL HYPERTENSION

Capt. Marvin Moser (MC), U.S.A.F.
Capt. James Syner
Capt. Sidney Malitz
and
Col. Thomas W. Mattingly, (MC), U. S. Army,
Washington, D. C.

Considerable publicity has recently been given to the newer hypotensive agents. The most promising of these drugs, hexamethonium, a ganglionic blocking agent, and hydralazine (Apresoline) hydrochloride, a sympathetic blocking agent with other complex actions, are now being used extensively in treatment of patients with essential hypertension.[1] A third compound, Dibenzyline (N-phenoxyisopropyl-N-benzyl-β-chloroethylamine) hydrochloride is an orally effective, sympathetic blocking agent that produces a fall in blood pressure when the patient is in an upright position, and is capable of preventing wide fluctuations in pressure as well as relieving symptoms.[2] All of these drugs may produce severe reactions if they are not used under controlled conditions. Grimson and his associates [3] and Schroeder [4] have recently published reports advising caution in the use of these drugs.

We have encountered numerous side-reactions of these three drugs, used either alone or in combination, in a group of carefully selected patients being treated for essential hypertension. Dibenzyline produced severe fatigue, marked persistent tachycardia, postural hypotension, persistent stuffy nose, and aspermia in several patients. In some patients hexamethonium administered orally or parenterally resulted in severe postural hypotension and syncope, difficult urination, constipation, and persistent blurring of vision. Marked tachycardia, headaches, vague muscle and joint pains, aspermia, nausea, and periorbital edema were experienced by

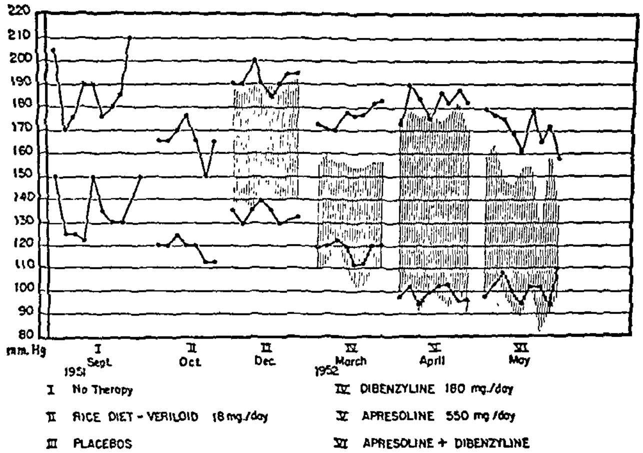
patients receiving hydralazine therapy. In addition, two patients receiving hydralazine noted episodes of transient euphoria, three experienced attacks of nervousness, and one, the subject of this case report, experienced a severe psychotic episode.

REPORT OF A CASE

A 44-year-old white man had hypertension of 28 years' duration. He had enjoyed good health until June, 1951, when he suffered a thrombosis of a branch of the left middle cerebral artery, with right hemiparesis, facial weakness, and spastic aphasia. There was a gradual clearing of the facial weakness and speech difficulty. No intellectual or unusual emotional changes were associated with this cerebrovascular episode. His blood pressure at that time presented a daily average of 220/130 mm. Hg. In September, 1951, prior to transfer to Walter Reed General Hospital, the patient was given a regimen of 18 mg. per day of Veriloid, a drug containing the hypotensive ester alkaloids of veratrum viride, and a rice diet for 45 days. He experienced a sense of well-being and a lowering of blood pressure to average readings of 165/118 mm. Hg. Substitution of placebos resulted in a rapid return of blood pressure to 200/130 mm. Hg.

In January, 1952, after arrival at Walter Reed General Hospital, the patient was given Dibenzyline in doses of 20 mg. three times daily. Dosage was gradually increased to 180 to 200 mg. per day. Initial side-reactions of nasal congestion, palpitations, and lightheadedness in the upright position partially cleared in 7 to 10 days. A fall in blood pressure to a daily average of 176/116 mm. Hg in the recumbent position and 154/108 mm. Hg in the upright position was obtained, with occasional low readings of 130/80 mm. Hg. During this period there were no episodes suggestive of mental deterioration or emotional instability.



Response of the blood pressure to therapy. Each section represents a 7 to 10 day period after the blood pressure had been stabilized by a particular drug. Each point represents an average of four to six readings per day. Shaded areas represent blood pressure with the patient in an upright position. (Psychotic episode occurred during April.)

Initial blood cell counts and urinalyses were normal and remained so throughout the patient's hospitalization. Studies of renal function revealed no abnormalities on admission or when repeated weekly. Funduscopic examinations and photographs revealed arteriolar spasm and narrowing with several small hemorrhages, a grade 3 retinopathy. Weekly examinations revealed some clearing of the hemorrhages and disappearance of arteriolar spasm with continuation of treatment. Chest roentgenograms showed moderate left ventricular hypertrophy, and repeated electrocardiograms showed a persistent abnormality indicating left ventricular hypertrophy with myocardial ischemia.

After approximately one and one-half months of Dibenzyline therapy, there was partial tolerance of the drug, with a gradual increase in recumbent blood pressure levels to 190/120 mm. Hg. Postural changes persisted.

On March 30, therapy with hydralazine, 25 mg. four times daily, was begun. The daily dose was progressively increased to 550 mg. per day, with the blood pressure and clinical response as a guide. The patient complained of a slight headache, which disappeared by the fifth day. When the daily dose reached a total of 350 mg. on the seventh day of therapy, there was a definite, improved sense of well-being characterized by increased mental alertness, cheerfulness, desire to return to work, and feelings of extreme confidence and resourcefulness. Whereas the patient had previously been reserved and uncommunicative with ward personnel, he became friendly. At this time blood pressure averaged 170/95 mm. Hg, with no significant postural changes. No alteration in blood chemistry or renal function was noted. The patient was discharged from the hospital, and his wife was taught how to measure blood pressure and to vary the dosage of hydralazine accordingly.

On the 10th day of hydralazine therapy, the patient experienced a sudden mood of depression with an outburst of intense crying. He felt dejected and gloomy but could offer no explanation for his feelings. An interview on his return to the hospital produced no evidence that this was a reaction to an adequate external cause or to internal difficulties. Cessation of the depressive mood was immediately followed by a feeling of cheerfulness and happiness. A sense of well-being developed, with gradual evolution into a mild degree of maniacal excitement. The patient experienced fantasies of tremendous physical and mental potential. These feelings and mood swings continued on the 11th day of therapy, but were not as marked.

On the 12th day of treatment, the patient, who was on a dosage schedule of 550 mg. of hydralazine per day, inadvertently took 200 mg. before breakfast, instead of the usual 100 mg. Within an hour he was in a delusional state characterized by fantasies of intellectual genius and unlimited ability to solve problems and prognosticate world affairs. He also had fantasies of making tremendous profits through clever business manipulations. The patient had auditory hallucinations in which he heard his own voice talking and planning "from within his head." He felt that he was receiving "divine guidance" for his exploits. Judgment was profoundly impaired. He approached strangers and offered advice. He rejected all appeals to reason by his wife and grew angry and irritable when she attempted to correct his delusional impressions. Violent episodes of anger alternated with periods of intense crying. The patient later recalled that his thoughts flowed at such a tremendous pace that he was unable to keep up with all of them. Blood pressure readings at this time were 160/95 mm. Hg when the patient was in a recumbent position and 150/90 mm. Hg in the upright position.

Hydralazine administration was discontinued, and, within 8 to 12 hours, there was marked remission of symptoms and a return of the personality toward normal. Within 24 hours the patient was psychiatrically asymptomatic and completely rational. For the next month he was maintained on a combination of small doses of hydralazine, 100 to 150 mg. per day, and Dibenzyline, 80 to 120 mg. per day, with a satisfactory blood pressure effect, and remained free of any untoward emotional side-reactions. Medication was then changed to a combination of 2 gm. of hexamethonium chloride (Methium) administered orally and 200 mg. of hydralazine, because of the development of a partial tolerance of the Dibenzyline and hydralazine combination. The patient received the new medication for two months with a satisfactory blood pressure response. He appeared to be well adjusted except for occasional periods of depression.

About three months after his initial psychotic episode the patient experienced a complete breakdown. This followed a sudden feeling of inadequacy in performing routine assignments at his job. He became severely depressed and suicidal and was admitted to the psychiatric service for treatment. The patient remained depressed for several months and made little progress until he was given doses of insulin producing subcoma. His feelings of inadequacy extended to include relationships with his family and friends as well as his career activities. All drug therapy was stopped after the episode of depression, and recent blood pressure levels have averaged between 190/120 and 240/140 mm. Hg. During the entire period of observation the patient's urinary output was normal, and repeated renal function studies did not reveal any abnormalities. Neurological examinations were essentially normal.

COMMENT

A relationship between the first psychotic episode in this patient and a specific drug has been shown. The patient showed evidence of basic personality changes while receiving daily dosages of 350 mg. of hydralazine. Psychotic manifestations were noted when the total daily dose was increased to 550 mg. After the patient took a single large dose of 200 mg. of hydralazine by mistake an acute psychotic episode, characterized by manic type behavior, occurred. With cessation of the drug there was marked improvement in 12 hours and complete reversion to normal in 24 hours. This patient had been maintained with several other medicaments during four months of hospitalization and was not particularly sensitive to drugs. He had periods of acute hypotension while receiving Dibenzyline and for a brief period while he was being tested with parenterally administered hexamethonium, but he had not experienced emotional outbursts or aberrations. During the acute psychosis with hydralazine treatment, blood pressure was not unusually low. We felt, therefore, that the episode was not secondary to marked alterations in cerebral blood flow. Renal function and blood chemistry remained within normal limits. The psychotic episode apparently represented a manifestation of hydralazine overdosage. Since the progression of the personality changes was carefully observed and the relationship of drug administration to the psychosis was well established clinically, we did not feel that the occurrence was coincidental or that it was necessary to reproduce the severe symptoms by readministration of large doses of hydralazine.

Several months later the patient had a severe depressive reaction that required a prolonged psychiatric hospitalization. This reaction did not appear to be related to drug effect and was not altered by the withdrawal of all medication. It seemed to be closely related to serious unresolved personality problems, which may have been aggravated by the patient's continuing hypertensive cardiovascular disease; that is, his feelings of inadequacy may have been directly related to his illness and lack of ability to cope with problems that formerly would have been quite simple.

It is logical to assume that the initial psychotic episode might not have occurred in a stable person, despite an overdose of a potent drug that apparently has a "central" action. (We have observed another patient who inadvertently took 600 mg. of hydralazine in a single dose and experienced no unusual psychiatric manifestations.) The previous adjustment of our patient was a tenuous one because of unresolved personal problems, and he was, therefore, susceptible to a break with reality in stressful situations. Similarities between his psychiatric symptoms and those described as following withdrawal of cortisone and corticotropin are striking and consist of hallucinations, delusions, extreme variations in mood, ideational flight, and depressive states.[5] Apparently some potent pharmacological agents are capable of altering physiological mechanisms in areas of psychogenic responses and may embarrass or decompensate an already precarious stability. These agents should be used with care, and the physician should be constantly aware of the possibility of precipitating a "breakdown of defenses" with a resulting psychotic episode.

The occurrence of acute anxiety episodes in patients with poor renal function and uremia, and who were receiving hydralazine, has been noted by Schroeder.[4] These personality alterations usually did not occur or were transient in patients without renal disease. In our case, euphoria continued for a longer period than is expected in such conditions, and an episode of mania was produced by a large dose of hydralazine. It is possible that the patient's mental state would have gradually returned to normal, even though he was maintained on 500 to 550 mg. per day, if he had not taken the extra dose of the drug. The psychological manifestations noted in this patient during hydralazine therapy, as well as the euphoria that occurred in other patients with this therapy, may provide additional evidence that the drug affects the higher cerebral centers.

SUMMARY

A case of acute psychosis as a result of hydralazine (Apresoline) overdosage in a patient with essential hypertension is reported. This episode apparently was not related to change in blood pressure or to renal function. Clinical recovery followed in 12 to 24 hours after withdrawal of the drug. This episode may have resulted from a release of basic personality conflicts after the disease state had been altered by the drug. The subsequent severe prolonged depression that was unrelated to hydralazine therapy substantiates this explanation.

Although hydralazine is a useful agent for treatment of essential hypertension, its administration, especially in outpatients and in unstable persons, should be carefully controlled. It is suggested that administration of this drug, as well as other agents used in the treatment of hypertension, be discontinued or the dose reduced if personality changes occur.

James Lind and the Treatment of Scurvy.—On completion of his medical apprenticeship in 1739, Lind entered the British navy as a surgeon's mate. . . . Up to Lind's time a number of books and papers had been written about scurvy, and in fact many had suggested the use of fruit juices for the prevention and treatment of the disease. It is to Lind's credit, and an example of his honesty and integrity, that in all of his writing he appreciated this fact and gave due recognition to the earlier observations. . . . In 1747, Lind carried out his experiment which proved conclusively that orange or lemon juice was a specific treatment for scurvy. . . . Not only did Lind demonstrate in a controlled experiment the importance of citrus juices in the treatment of scurvy, but his practical and inventive mind led him to develop an improved method for the preservation of citrus juice, a significant development in food technology. . . . Despite the excellence of Lind's results, his official position in the Royal Navy, and his detailed report in the "Treatise on the Scurvy" published in 1753, it was not until almost 50 years later (1795) that the Admiralty finally gave orders for the compulsory issue of lemon juice to all ships. This "perversity of officialism" and gross governmental inefficiency undoubtedly resulted in a loss of life from scurvy during this period greater than that from all other causes of seamen's deaths put together.—W. A. Krehl, James Lind, M.D. (October 6, 1716—July 18, 1794), *Journal of Nutrition*, May, 1953.

TELEPAQUE AND PSEUDOALBUMINURIA

E. E. Seedorf, M.D.
W. N. Powell, M.D.
R. G. Greenlee, M.D.
and
D. N. Dysart, M.D., Temple, Texas

Since the occurrence of pseudoalbuminuria after ingestion of iodoalphionic acid (Priodax) [1] and Monophen (2-[4-hydroxy-3,5-diiodobenzyl]-cyclohexane carboxylic acid) [2] was reported, another cholecystographic medium, Telepaque (3-[3-amino-2,4,6-triiodophenyl]-2-ethylpropanoic acid), has been employed successfully. Telepaque is a solid containing 66.68% iodine, while iodoalphionic acid contains 51.5% and Monophen 52.2% iodine. Experiments with animals at the Sterling-Winthrop Research Institute have shown that Telepaque, taken orally, is eliminated mainly by the gastrointestinal tract but to some extent by the kidneys.

As a fairly high incidence of pseudoalbuminuria was found after ingestion of iodoalphionic acid and Monophen,[2] study of Telepaque was undertaken to determine whether the small amount of this drug eliminated through the urinary tract was sufficient to cause pseudoalbuminuria. Chemical examination of the substance showed that it readily dissolved in water. When the solution was acidified, a flocculent precipitate appeared, and, when it was alkalized, the precipitate disappeared.

Over 100 patients received Telepaque, but only the first 100 (40 men and 60 women) to meet all the requirements were accepted for this study. Reasons for rejection were: the presence of albumin in the routine urinalysis before the medium was ingested; urine specimen not presented for examination before ingestion of the medium, the day after ingestion (day of gallbladder examination), and the day after the gallbladder examination; and menstruation.

The manner of administering Telepaque to the patients was similar to that used for the other cholecystographic mediums. Telepaque was given in four tablets, a total dosage of 2 gm. It had been established that this amount produced cholecystograms of as great or greater density than six tablets of iodoalphionic acid or six capsules of Monophen. As in the previous studies on iodoalphionic acid and Monophen, Exton's reagent, Heller's ring test, Robert's reagent, and nitric acid and heat were used to examine urine for the presence of albumin.

Table 1 shows the number and/or percentage of false positive reactions for albuminuria when hot Exton's reagent was used. This is the most significant portion of the table, as the Exton's test is the one most universally employed for the detection of albuminuria. Of the 100 patients, whose preliminary urinalyses showed no evidence of albumin, 15% had positive Exton's tests (pseudoalbuminuria) after the ingestion of Telepaque. This compares closely with the 14% incidence found with iodoalphionic acid and the 17% with Monophen in our earlier study.[2] Although the urine and Exton's reagent mixture should be observed while hot, it is interesting to note that when the result is read after the solution has cooled the incidence of positive results increases considerably.

A preliminary urinalysis negative for albumin with hot Exton's solution was obtained on all patients before any gallbladder medium was given; however, preliminary urinalyses with the other albumin-testing reagents were not obtained before the medium was given. In order to correctly evaluate these reagents we ran a control group of 100 urinalyses. The control patients received no gallbladder medium and their urine specimens were negative to the routine Exton's test. When the Exton's reagent was cool, a false positive result was observed in nine specimens. All were negative to Heller's test. The nitric acid and heat test gave a positive reaction in 20 specimens, and Robert's reagent showed 9 to be positive. *In our opinion Exton's reagent is the most selective test for true albuminuria.*

TABLE 1.—*Incidence of Pseudoalbuminuria Following Ingestion of Iodoalphionic Acid (Priodax), Monophen, and Telepaque**

Laboratory Test	Control Group with No Medium	% Positive with		
		Iodoalphionic Acid †	Monophen †	Telepaque
Exton's reagent (hot)..	0	14	17	15
Exton's reagent (cold).	9	60	65	43
Heller's ring test.......	0	10	10	1
HNO_3 and heat test...	20	43	39	36
Robert's reagent.......	9	72	82	15

* Each medium was given to a separate group of 100 patients.
† Studies of these mediums were previously reported.[2]

TABLE 2.—*Side-Reactions Following Ingestion of Iodoalphionic Acid (Priodax), Monophen, and Telepaque**

Side-Reaction	Iodoalphionic Acid †	Monophen †	Telepaque
Dysuria	48	23	29
Diarrhea	38	13	39
Abdominal cramps.................	21	19	29
Headache	21	27	29
Nausea	17	28	17
Dizziness	15	14	16
Allergic phenomena................	4	7	4
Visual disturbance.................	2	4	6
Vomiting	0	0	1
Miscellaneous reactions............	4	0	4

* Each medium was given to a separate group of 100 patients.
† Studies of these mediums were previously reported.[2]

In general, it can be said that some specimens from the control group were positive to the nitric acid and heat test and to Robert's reagent. Nevertheless, the incidence of positive reactions was greater after the ingestion of any of the three mediums. This indicates that all of the albumin-testing reagents are likely to produce some false positive reactions for albuminuria after the ingestion of these gallbladder mediums.

Iodoalphionic acid and Monophen are eliminated primarily by the urinary system,[3] while Telepaque is reported to be eliminated primarily by the gastrointesti-

nal tract.[4] We anticipated a reduced incidence of dysuria and an increased incidence of diarrhea with the use of Telepaque, but our results failed to support this assumption. In general, the frequency of side-reactions was relatively the same after the use of all three mediums.

In this study, as with iodoalphionic acid and Monophen, the presence or absence of pathological findings on the cholecystogram was not related to the occurrence of pseudoalbuminuria. The urine specimens of four patients continued to show presence of Telepaque for three days after ingestion, but were free of the drug on the fourth day. Apparently, because of the greater amount of dye in proportion to body weight, the incidence of pseudoalbuminuria was higher in the lighter weight patients.

As mentioned previously, only 2 gm. of Telepaque gave a gallbladder shadow of as great or greater density than 3 gm. of iodoalphionic acid or Monophen; 97 of the 100 cholecystograms showed normally functioning gallbladders, and 3 cholecystograms showed nonfunctioning gallbladders. Calculi were visualized on seven of the films showing normal function and on two of the films showing nonfunctioning gallbladders.

From extensive experience, we have established what we consider the average normal density of cholecystograms produced with iodoalphionic acid. In our series with Telepaque, we considered about one-half of the cholecystograms slightly to considerably denser than those produced with the other two mediums. The cystic duct was visualized in 10 patients; 9 had gallbladder shadows of increased density. Whereas, the denser gallbladder shadow produced by Telepaque has certain advantages, it may also produce too dense a shadow, obscuring gallstones. We have not encountered this difficulty with the dosage employed. Unlike the other two mediums, Telepaque is commonly seen in the gastrointestinal tract for two or three days after ingestion. It can usually be distinguished from gallstones when it overlies the gallbladder, but in 13 of our patients it was necessary to make that distinction. In our clinic, abdominal flat plates and lumbar spine roentgenograms are usually made after cholecystography. A residue of Telepaque was seen in 92 patients who had roentgenograms of the abdominal region after cholecystography, and occasionally, another film was necessary to exclude the possibility of urinary or other abdominal calculi.

SUMMARY

Since the incidence of pseudoalbuminuria is high enough to cause erroneous impressions, urinalyses taken on the day after and, occasionally, two or three days after cholecystography employing iodoalphionic acid (Priodax), Monophen (2-[4-hydroxy-3,5-diiodobenzyl]-cyclohexane carboxylic acid), or Telepaque (3-[3-amino-2,4,6-triiodophenyl]-2-ethylpropanoic acid) should be interpreted with caution. Side-reactions and their frequency were relatively the same after the use of all three mediums but were not severe enough to contraindicate use.

Good cholecystograms were produced by all three mediums. In our experience, a smaller dosage of Telepaque than of the other two mediums was advantageous. Undesirable results of the use of Telepaque were a residual deposit in the bowel and occasional interference with interpretation of renal or other calculi.

METHOD AND MACHINE FOR RESUSCITATION OF THE NEWBORN

John Mann, M.D., Toronto, Canada

One of the objections to mechanical resuscitators in general is that in their use oxygen is applied to the infant by face mask without investigation of the condition of the airway. It is obvious that not only is any machine that is applied to a child who has an obstructed airway ineffective but the time loss due to airway obstruction may be fatal. The establishment and maintenance of a free airway is of first importance; without it no method can succeed. The entire respiratory tract must be cleared of obstructing fluid or mucus. Obstruction due to spasm of the glottis, if present, must be overcome. This condition may result from an irritating mucus plug or from certain types of anesthetic agents administered to the mother. Infants in the stage of flaccidity with collapsed glottic structures and absent reflexes may also have obstructed airways. Intubation of the trachea is the only method of dealing with these situations.

There is considerable controversy over the ease and safety of intubation. Much of this controversy is a result of a gross misunderstanding of the problem at hand. There are two points to be made: 1. In cases where obstruction is definitely present intubation must be done whether it is easy or difficult. 2. The procedure of intubating the infant has been madė unnecessarily difficult owing to a lack of understanding of a few simple principles. The commonest mistake is that of lowering the head over the edge of the table to put it in a position of hyperextension, supposedly to help visualize the glottis. This is an incorrect procedure.

METHOD OF INTUBATION

The child should lie flat on its back, with the back of the head flat on the table. The tip of the blade of an infant laryngoscope (Foregger is my preference) is inserted to the glottis. The handle of the laryngoscope is then lifted vertically. This brings the glottis to view, and the catheter is inserted without trauma.

There are still some who object to intubation but practice mouth-to-mouth insufflation. The inadequacies and dangers of this method include the lack of control of the pressure applied. When intubation is a must, the tracheal catheters herein described give maximal efficiency and safety in use.

THE MACHINE

The machine, which is entirely manually controlled, has been devised to overcome the objections to automatic devices, many of which contain multiple working parts, resulting in the machine frequently getting out of order. Dependability is essential in a machine used mainly in emergency. Owing to the danger of oxygen

---

From the Department of Obstetrics and Gynecology, University of Toronto.

delivery by mask, the machine is supplied with equipment for tracheal intubation to permit suction clearing and the direct administration of intratracheal oxygen. Mask attachment is also supplied for use when intratracheal administration is unnecessary.

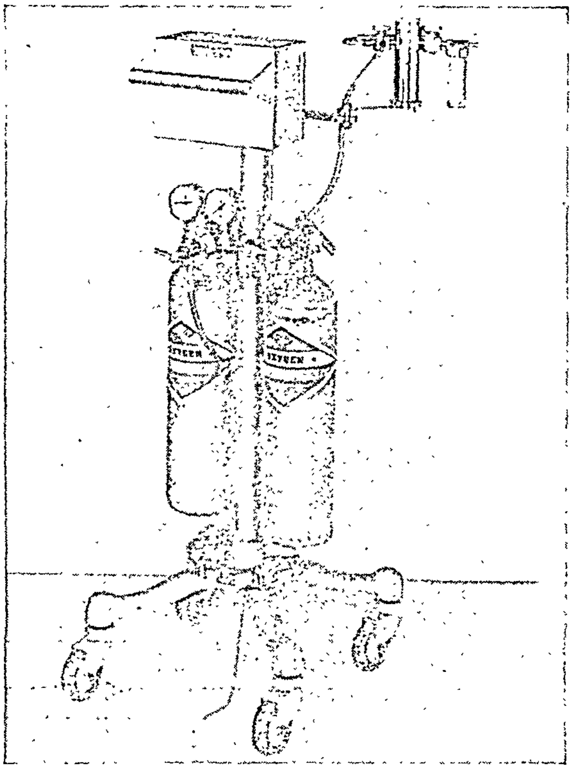

Fig. 1.—Machine used in resuscitation of the newborn infant.

The machine is a self-contained unit mounted on a heavy base with freely wheeling casters (fig. 1). Oxygen is supplied from two tanks, one in operation and the second a spare, always available. The oxygen is delivered to the resuscitation head through a standard reducing valve. A small built-in cabinet provides storage space for a laryngoscope and spare batteries, intratracheal catheters in graduated diameters, no. 4, 5, 6, and 7 (fig. 2), and a face mask. The head consists of a manually controlled suction bulb for removal of mucus; a removable, transparent, plastic drainage trap (no mucus can enter the oxygen administering valve), and a resuscitating valve of a simple, single chamber, two port, ball valve construction. It is simply a positive and negative resuscitating safety valve. The valve is a ball type, bronze construction. There are no washers, springs, hinges, or any other parts to get out of order or require replacement. In construction, the valve is designed to deliver a positive oxygen pressure of 12 mm. Hg and a negative pressure of 8 mm. Hg. No setting is necessary, and no change of these pressures can be made. Even with gross pressure ranges at the reducing valve these positive and negative pressures applied to the infant cannot be altered. Any excess oxygen merely escapes into the air.

The administration of oxygen and the switch to negative pressure is regulated by a manual control marked positive and negative. The rate of alternation from positive to negative pressure is entirely under the operator's control, which is a distinct advantage over automatic control. The manual control regulates the rate of alternation only. When on positive, the pressure is always 12 mm. Hg, never more nor less. Similarly, on negative, the pressure is always 8 mm. Hg, never more or less. There is no neutral or dead spot on the control. It is either positive or negative. (The negative pressure is created from the positive reduced tank pressure by the Venturi attachment.) No two resuscitation problems are alike. Each case requires individual treatment, which cannot be accomplished by automatic mechanical devices. The sooner this fact is realized and accepted the sooner will resuscitation salvages increase and disasters be avoided.

APPLICATION OF THE APPARATUS TO THE METHOD OF RESUSCITATION

As soon as the child is delivered, mucus should routinely be removed from the nasal passages and pharynx. If the infant does not breathe spontaneously there is no use wasting time with obsolete dangerous methods, nor is it permissible to attempt the administration of oxygen to an infant until a clear airway has been established. The passage of an intratracheal catheter is a procedure that requires more gentleness than skill. The minimal amount of manual dexterity required for introducing the catheter can readily be accomplished by anyone who has arrived at the station of assuming the responsibility for the care and management of the newborn infant. The catheters supplied with the apparatus greatly facilitate this procedure. The catheters are supplied in graduated diameters, and the length from hilt to tip is designed to permit an adequate descent into the trachea without encroachment on the coruna. They are metal and designed to prevent trauma. The metal construction provides rigidity to facilitate control, and the thin wall permits a maximal lumen. The hilt provides a side handle that removes the

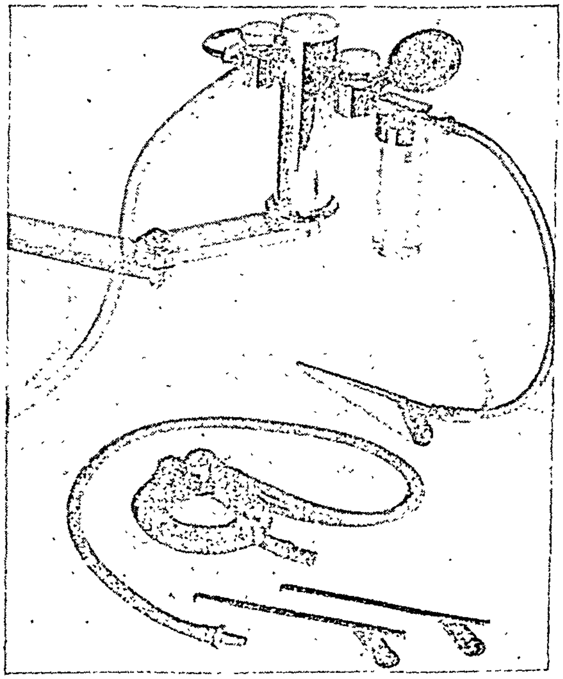

Fig. 2.—Intratracheal catheters in graduated diameters and the head of the resuscitation machine.

operator's fingers from obstructing the field of vision during insertion.

With the catheter in place the suction valve is opened, bulb section is applied to remove mucus, and the suction valve then closed. With the reducing valve registering about a 3 to 4 liters per minute flow of oxygen, the alternating positive and negative pressures to instigate respiratory movements are under the operator's control. Alternations of 10 to 15 per minute are adequate and give the child a much better chance of establishing his own respiratory rate than more rapid artificial movements. As long as the child's color is improving, the depth of respiratory movements is of no concern. The apparatus is delivering to the lung alveoli 100% oxygen. When respirations are established the catheter is removed. If the child is not robust and additional oxygen is indicated it may be administered with the face mask. A longer tube for attachment to the mask is provided for administering continuous oxygen to the child in the crib if necessary.

This apparatus and method of resuscitation is accepted and endorsed by the department of obstetrics and gynecology and the department of anesthesia, University of Toronto, Canada. In the two years that the instrument has been used in the Toronto General Hospital it has never been found to be out of order. There have been no mechanical breakdowns of any kind and no maintenance or service work required. This continued performance may be expected indefinitely. There has been no occasion to alter in any way the original design of the machine.

TEACHING AUSCULTATION BY ENDLESS LOOP TAPE RECORDING

George D. Geckeler, M.D.
William Likoff, M.D.
and
Daniel Mason, M.D., Philadelphia

Auscultation is the most satisfactory means of evaluating heart sounds and murmurs. The object of modern teaching is to bring about proficiency in auscultation through good training. It still remains a contemporary practice, however, to teach auscultation to small groups of students at the patient's bedside. This method is entirely dependent on available clinical material, and it is not unusual for students to enter the practice of medicine without ever having heard the bruit of a patent ductus arteriosus or the sound of a pericardial friction rub. Even if the desired material is at hand, students frequently react to the pressure of colleagues who await their turn to listen by hurrying through the examination without understanding what is heard, or patients often resist these repeated examinations and encourage careless haste. When teaching is restricted to clinical material, an opportunity to compare different sounds and murmurs is seldom offered at the time confusion first arises. Unless the work at the patient's bedside is carefully guided, misconceptions become fixed errors. In providing the constant supervision necessary, a teaching staff may be heavily overburdened. It is possible to meet these problems in teaching by making use of reproductions of heart sounds and murmurs. These may be graphic or auditory.

Phonocardiography is the graphic registration of the vibrations of heart sounds and murmurs. When the recording is done with a stethoscopic microphone, a record is obtained of all the vibrations that would reach the ear through the stethoscope, including the low-pitched tones that are not actually heard. The logarithmic microphone records the vibrations of only those sounds that are actually heard. Regardless of which microphone is used, the written record cannot serve as a substitute for an actual auditory reproduction, for the sense of hearing is best trained by listening. It is obvious that the description of the taste of an apple is a poor substitute for the experience of eating the fruit. Teaching methods that use actual sound reproductions are the most efficient for teaching students and physicians the art of auscultation.

By means of a microphone that will respond to low frequency sounds, it is possible to record heart sounds and murmurs on phonograph records.[1] Rappaport and Sprague [2] have shown that practically all heart sounds and murmurs are less than 2,000 cycles per second and that adequate means to record these frequencies must be used. Since a special playback is not required, these records may be played wherever a phonograph is available. They make possible the demonstration of types of heart sounds and murmurs that may not be ordinarily available and, if an explanatory script is included with the recording of the heart sounds, an intimate form of teaching is preserved. Phonograph records, however, have several failings. Each record contains many types of heart sounds and murmurs. When demonstrating to a large group, it is difficult to find a specific illustration without including other, perhaps confusing, material. Furthermore, it is impossible to play any single example continuously so that it may be mastered by repetition. Experience has shown that phonograph records are beneficial for individual rather than for group instruction. Records may be kept in a small room with special acoustic features or in a special section of the medical library to be used by students as reference material to supplement or clarify auscultatory findings in a patient.

A student's difficulty in learning the technique of auscultation very often arises on occasions when the heart rate is too rapid to permit recognition of a murmur and when a murmur cannot be separated from the accompanying heart sound. Heart rates cannot be satisfactorily reduced, and murmurs cannot be separated from heart sounds on phonograph records. Teaching cardiac auscultation has been greatly improved by the use of endless loops of tape on which heart sounds, murmurs, and arrhythmias have been recorded. This method of instruction has been more effective in teaching large groups of students and physicians than has the bedside demonstration of patients and the use of phonocardiograms or phonograph records. It does not require visual or pal-

[2] Rappaport, M. B., and Sprague, H. B.: Physiologic and Physical Laws that Govern Auscultation, and Their Clinical Application: Acoustic Stethoscope and Electrical Amplifying Stethoscope and Stethograph, Am. Heart J. 21:257-318 (March) 1941.

patory teaching aids; although these aids may be used as adjuvants, we feel strongly that they should not be used simultaneously with the playing of heart sounds. Auditory, visual, and palpatory stimuli have different reaction times, and, if shown simultaneously with auditory phenomena, they may result in confusion rather than clarification.

METHOD

The apparatus and the method described have been used successfully at the Hahnemann Medical College of Philadelphia for teaching sophomore and postgraduate students since 1950. The original reel-to-reel tape recordings of normal and abnormal heart sounds, murmurs, and arrhythmias are made in the conventional manner using a dynamic microphone and a tape recorder. The recordings are made in a sound dampened or acoustically equipped room, and, when played back they sound quite like the auscultatory findings heard with a stethoscope.

From these reel-to-reel recordings, continuous loops may be constructed by splicing selected segments of tape that contain several cardiac cycles. If the heart rhythm is regular, this continuous loop is an accurate reproduction of what would be recorded from the precordium over a long period of time.

By means of phonocardiographic study, it has been possible to determine the time that elapses between the first and second heart sounds and between the second and next first heart sound, with the heart beating at different rates. The recording tape runs at a speed of 15 in. (38.1 cm.) per second. With these factors known, it is possible to determine the length of blank tape that must be spliced between the first and second and the second and next first heart sound in order to reduce the cardiac rate of any particular recording. The fidelity of the sounds and murmurs is not affected by this maneuver. Splicing blank tape between murmurs and heart sounds permits them to be heard separately.

APPLICATION

With the utilization of endless loop tape recordings and clinical material, it is routine practice at the Hahnemann Medical College to teach auscultation to sections of 40 students during eight two-hour sessions. All demonstrations are held in a specially equipped room. Two playbacks are connected in series to the loud speaker. An ordinary cut-in switch permits the demonstration of clinical material, by using a recording microphone with the edges sealed by ordinary rubber tubing. The patient to be demonstrated is well removed from the loud speaker in order to prevent feed-back. Students are instructed to listen for one thing at a time and to approach the auscultatory problem in a routine fashion. In such a manner, first the rhythm is recognized, then the nature of the first and second heart sounds, and finally the presence of systolic and diastolic murmurs. The continuous loop may be played for an indefinite period of time until each student has mastered its lesson. The sounds may be compared with those of any other tape to illustrate a similar or easily confused auscultatory abnormality. They may be compared with the available clinical material through the use of the microphone and cut-in switch. When rapidity of cardiac rate results in confusion, a tape with reduced heart rate may be substituted. For further clarification, murmurs can be played apart from the heart sounds. When this method and material are properly applied, a gratifying proficiency in auscultation may be acquired in a relatively short period of time. Students experience no difficulty in applying their knowledge to stethoscopic examination.

SUMMARY

1. The ordinary methods of teaching auscultation are reviewed, and their shortcomings are noted.
2. The apparatus used to produce endless loop tape recordings is described.
3. The method of producing endless loop tape recordings is described, as well as the method of producing recordings at reduced rates or with murmurs separated from other heart sounds.
4. The advantages of teaching with endless loop recordings are cited.

249 N. Broad St. (7) (Dr. Likoff).

CAUSES OF DISABILITY IN PATIENTS WITH CHRONIC DISEASE

Joseph I. Goodman, M.D., Cleveland

Because interest in the chronic diseases has developed only recently, publications dealing with this subject are scarce. My long experience with chronically ill patients at the Cuyahoga County Nursing Home is, therefore, worthy of presentation. When this large 160 bed, publicly operated institution was established in 1939, a favorable opportunity to observe and study chronic disease was created. Many data on this increasingly important category of diseases have been accumulated during the 13 years that I have been the medical chief at the nursing home.

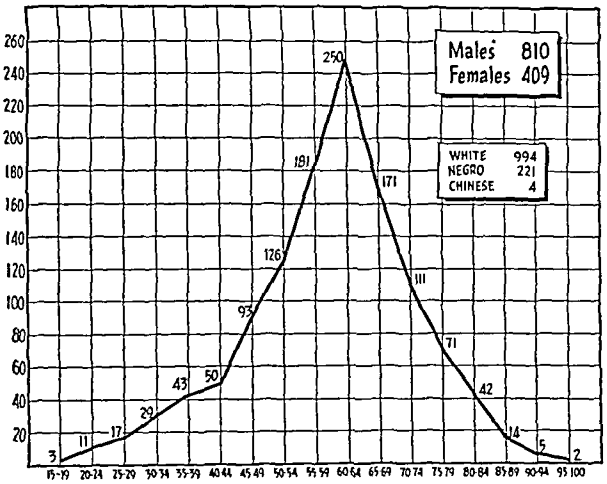
The present study deals with 1,219 patients, many of whom were given an autopsy, admitted to the home between February, 1939, and December, 1952. In accordance with state regulations, patients admitted to the nursing home are permanently and totally disabled and require active medical supervision and intensive nursing care. Persons with infectious diseases, tuberculosis, or psychoses are ineligible for admission. The type of disabilities found in this chronically ill group does not bear out the prevailing opinion that the leading causes of disability are the degenerative diseases, e.g., cardiovascular diseases, renal disturbances, and arthritis. The patients, preponderantly indigent, are usually referred to the nursing home by a private physician or a general hospital. Because the diagnostic facilities are limited, a complete study of each patient in a general hospital is a prerequisite to admission. Every new patient is examined thoroughly by the resident physician and me. Consultants in neurology, cardiology, and rheumatology make regular visits to the institution. Partly because of the limited diagnostic facilities, but mainly because of the orientation of the staff members and consultants, physical diagnosis has been emphasized. As a result, new diagnostic criteria have been developed in the patients at the home. Infor-

---

The statistical data for this study were compiled under the direction of Dr. Anna Lewin with the assistance of Dr. B. A. Treister, Director of Physical Medicine, Ursula Rist, Superintendent, Dr. George A. Csanad, and Grace Matsushima.

mation from previous hospital records is incorporated with all other pertinent medical data into the patient's record. Before a definite diagnosis is decided on, the consultants' opinions are taken into consideration. Of course, some diagnoses are changed after a period of observation in the home, but, in the last analysis, the final diagnosis of these patients has been scrutinized most carefully.

The age distribution curve of the 1,219 chronically disabled patients in this study is shown in the figure. The 60 to 64 year category is the peak age, though it can be seen that over one-half of the patients are 50 to 69 years of age. Actually two-thirds of the patients exceed 55 years in age, which is in keeping with the increasing longevity of the present-day population. Although the sex ratio indicates a 2:1 preponderance of males over females in this series (see figure), these figures are not truly representative of the actual sex ratio of chronic illness. It so happens that the wards at the nursing home have been arranged to accommodate twice as many males, thus accounting for their predominance over females. In view of the 1:4 ratio of Negro to white patients, as compared with an approximately 1:10 ratio in the population at large, it appears that chronic illness is more prevalent in the former.



Age distribution of 1,219 nursing home patients from Feb. 1, 1939, to Aug. 1, 1952.

For the purpose of this study, a special analysis of the major disabling conditions in 431 consecutive patients admitted to the nursing home between January, 1946, and July, 1952, has been made. Having been observed more recently than the group as a whole, i.e., within the past six years, this group has benefited from the newest developments in diagnosis, treatment, and classification of disease. Because of great uniformity in the interpretation of the findings, the conclusions drawn in the smaller group of 431 cases are probably more accurate. Nevertheless, I believe the deductions are equally applicable to the entire series and, in fact, to any comparable series of chronically ill patients. Another reason to accept the validity of the deductions in the smaller group is the remarkable similarity of the age distribution curves of the 431 patients in this report and that based on the 1,219 patients.

PRIMARY DISABILITIES

Multiple diagnoses were the rule in the present group of chronically ill patients. Only the patients' major disease is recorded in the table, the secondary disabilities and concomitant diseases being tabulated elsewhere. For example, in a patient with carcinoma of the lung in whom generalized atherosclerosis is also present, the former is

Major Causes of Disability of 431 Patients Admitted to County Nursing Home

		No. of Cases	%

regarded as the major disability and is recorded in the table, while the latter diagnosis does not appear.

It may come as a surprise to many that over one-half, or 51%, of the patients with chronic disability are affected primarily by a disorder of the nervous system. Since patients with psychoses are not accepted in the nursing home, the great majority of these patients have neurological disorders. The commonest neurological disability, by far, is the cerebrovascular accident (hemiplegia, stroke, or apoplexy), affecting one out of five patients admitted to the home. Also, this disorder constitutes the greatest single disability in two out of every five patients with neuropsychiatric diagnoses. Because the majority of the cases of cerebrovascular accident are caused by thrombi secondary to cerebral atherosclerosis, such patients may also be classified under atherosclerosis. Other frequently encountered neurological disabilities are diseases of the basal ganglions, central nervous system syphilis, multiple sclerosis, and peripheral neuropathy, although it can be seen in the table that almost every known neurological entity can be found among this large segment of admissions.

Second to the neuropsychiatric impairments in importance are malignant tumors, mainly carcinomas, which constitute 17% (75 cases) of the 431 patients in this study. The significance of this condition as a leading cause of prolonged disability requires no further comment. In third and fourth places, respectively, among the leading cause of prolonged disability are two other sequelae of atherosclerosis, namely, amputations and congestive heart failure. Still, compared to the frequency of the neurological diseases and malignancy, the relatively low incidence of these two conditions is worthy of note. This also holds true for rheumatoid arthritis, the fifth ranking cause of disability in this series. Because this condition can be so disabling, an institution such as the nursing home, so well suited to the management of such patients, receives a large share of the cases in this community. In view of this, the low incidence of rheumatoid arthritis, compared with the other conditions treated at the home, is totally unexpected. Actually advanced malnutrition (starvation) proves to be the sixth commonest primary disability in this series of patients. Although there were nine such cases, or 2%, in the group, these figures do not emphasize adequately the true importance of malnutrition in patients in whom other diseases have been listed as the major disability.

The remaining major disabilities listed in the table are scattered among many unrelated diseases. Despite its prevalence in the general population, hypertrophic arthritis proves to be a no more frequent cause of primary disability than cirrhosis of the liver, bone tuberculosis, chronic venous insufficiency, deafness, and blindness. In contrast to its high incidence in the general population, diabetes mellitus per se is not a disabling condition. The leading complications of diabetes producing disability, i.e., gangrene and coronary artery disease, are classified here under these categories when they occur and not under diabetes mellitus. There was an extremely low incidence in these patients of diseases of the gastrointestinal tract and the hematopoietic system as major disabilities.

The apparent discrepancy between the high incidence of atherosclerosis in patients of these age groups at autopsy and their low incidence as a cause of disability in this study deserves comment. The data in living disabled patients do not necessarily conflict with the postmortem findings, since there is also a very high incidence of proximal, peripheral, and coronary atherosclerosis (65% of the patients). It should be pointed out, however, that a patient with atherosclerosis is not disabled until one or more arteries supplying a vital area are occluded. Inasmuch as this study deals with functional impairment only, the incidence of disability following arterial occlusion as reported here need not parallel the frequency of atherosclerotic complications found at autopsy.

In the present study when all the major disabilities caused by atherosclerosis, i.e., thrombotic cerebrovascular accidents, cardiac failure, and amputations, are combined, they add up to 30% of the 431 patients. On further analysis it is found that two-thirds of these cases are cerebrovascular accidents and the remaining one-third are divided between cardiac failure and amputations. One must conclude, therefore, that as a cause of disability the cerebrovascular accident is far more prevalent than coronary sclerosis despite the high rank of the latter as a cause of death in this country.

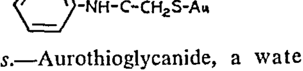
COUNCIL ON PHARMACY AND CHEMISTRY

NEW AND NONOFFICIAL REMEDIES

The following additional articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its action will be sent on application.

R. T. Stormont, M.D., *Secretary.*

Aurothioglycanide.—Lauron (Endo).—α-Auromercaptoacetanilid.—C_8H_8AuNOS.—M.W. 363.42.—The structural formula of aurothioglycanide may be represented as follows:



Actions and Uses.—Aurothioglycanide, a water-insoluble gold compound, is used for the treatment of rheumatoid arthritis on the same basis and subject to the same precautions as water-soluble salts of gold. (See New and Nonofficial Remedies under the section on gold compounds). Aurothioglycanide is absorbed more slowly from the tissues than are water-soluble gold compounds and produces fewer untoward reactions, but it should be employed with similar caution to avoid the possibility of toxic reactions. It has not been shown to be more effective than other gold compounds. Careful supervision, repeated laboratory examinations which will reveal signs of gold intoxication, and avoidance of exposure to sunlight, ultraviolet rays, or x-rays are essential as with the use of other forms of chrysotherapy.

Dosage.—Aurothioglycanide is administered into the gluteal muscle by injection of a suspension in oil. The initial dose should not exceed 25 mg. This is gradually increased as tolerated by increments of not more than 25 mg. administered, at weekly intervals for 22 weeks. However, a maximum single dose of 150 mg. should not be exceeded. When untoward effects are observed, the schedule of weekly injections should be interrupted until such manifestations have disappeared.

Tests and Standards.—

Physical Properties: Aurothioglycanide is a grayish-yellow powder, m.p. 238.0-241.0°. It is insoluble in acids, bases, benzene, ether, chloroform, and water.

Identity Tests: The procedure described for the determination of gold under Assay serves as an identity test.

Place in a test tube about 15 mg. of aurothioglycanide. Add 5 ml. of a 4% solution of selenium oxychloride in sulfuric acid: a deep red color develops (*presence of gold*).

Purity Tests: Dry about 1 gm. of aurothioglycanide, accurately weighed, at 105° for 4 hours: the loss in weight does not exceed 0.2%.

Assay: (Gold) Transfer to a porcelain crucible about 0.3 gm. of aurothioglycanide, accurately weighed. Heat slowly, to avoid splattering, until the compound is completely decomposed, then increase the heat until a homogenous residue of metallic gold is obtained. Cool in a desiccator and weigh. Each gram of gold formed is equivalent to 1.843 gm. of aurothioglycanide. The amount of gold is not less than 53.3 nor more than 55.0%, equivalent to not less than 98.0 nor more than 101.0% of aurothioglycanide.

Dosage Forms of Aurothioglycanide

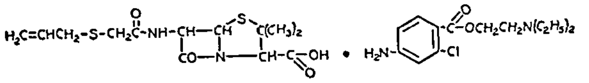
SUSPENSION. *Identity Tests:* The suspension responds to the identity tests for the active ingredient in the monograph for aurothioglycanide.

Assay: (Gold) Transfer to a tared sintered glass crucible of fine porosity an amount of suspension, accurately measured, equivalent to about 0.45 gm. of aurothioglycanide. Filter by suction and wash the aurothioglycanide with five 10 ml. portions of acetone. Proceed as directed in the assay for gold in the monograph for aurothioglycanide starting with, "Heat slowly to avoid splattering . . ." Each gram of gold formed is equivalent to 1.843 gm. of aurothioglycanide. The amount of aurothioglycanide is not less than 95.0 nor more than 105.0% of the labeled amount.

Endo Products, Inc., Richmond Hill, N. Y.

Suspension Lauron in Oil: 5 and 10 cc. vials. A suspension in sesame oil containing 50 and 150 mg. of aurothioglycanide in each cubic centimeter. U. S. patent 2,451,841. U. S. trademark 398,432.

Chloroprocaine Penicillin O.—Depo-Cer-O-Cillin Chloroprocaine (Upjohn).—A crystalline salt of 2-chloroprocaine and penicillin O. The structural formula of chloroprocaine penicillin O may be represented as follows:



Actions and Uses.—Chloroprocaine penicillin O, a water-insoluble salt of penicillin O, has the same spectrum of antibacterial activity as other salts of penicillin O and penicillin G. (See New and Nonofficial Remedies under the monographs on penicillin G and potassium penicillin O.)

The intramuscular injection of chloroprocaine penicillin O, as a suspension dispersed in water, results in the formation of a depot of penicillin O, similar to that produced by corresponding preparations of procaine penicillin G. The levels of antibiotic in the blood produced by intramuscular injections of an aqueous suspension of chloroprocaine penicillin O are approximately equal to those obtained by a similar injection of an aqueous suspension of procaine penicillin G. With aqueous chloroprocaine penicillin O, the levels of the antibiotic in the blood usually persist for about 24 hours as compared to 12 to 18 hours with aqueous procaine penicillin G.

As with soluble salts of penicillin O, the majority of patients sensitive to salts of penicillin G will tolerate chloroprocaine penicillin O without allergic reactions; however, some patients may be sensitive to both penicillin G and penicillin O. In such patients another antibiotic should be used.

Dosage.—Chloroprocaine penicillin O is administered intramuscularly as an aqueous suspension containing 300,000 units per cubic centimeter. In acute staphylococcic, streptococcic, and pneumococcic infections, the minimum dosage is 300,000 units injected once daily and continued until the temperature has returned to normal for at least 48 hours and evidence is present that the infection is disappearing. When these infections are severe, 600,000 units every 12 hours may be employed, or replaced by injections of a solution of potassium penicillin O at shorter intervals. In acute gonorrhea, a single injection of 300,000 units is usually sufficient to effect a cure, but patients who fail to respond should be retreated until a cure has been achieved. In chronic gonorrhea accompanied by complications, higher doses and more prolonged therapy may be required. In the treatment of gonorrhea the possible masking effect of penicillin on the early signs of syphilis should be kept in mind; appropriate tests should be instituted to confirm or exclude the presence of that disease.

Aqueous suspensions may be kept at room temperature for three weeks without a significant loss of potency and without caking. If refrigerated, the suspension should be gradually warmed prior to injection and shaken vigorously to make certain that all of the penicillin is in suspension. Excessive heating should be avoided to prevent destruction of the physical or antibacterial properties of the suspension.

The Upjohn Company, Kalamazoo, Mich.

Depo-Cer-O-Cillin Chloroprocaine: 1,500,000 unit vials of chloroprocaine penicillin O. U. S. trademarks 515,760 and 554,422.

Estrone-U.S.P. (See New and Nonofficial Remedies 1953, p. 357).

Eli Lilly & Company, Indianapolis.

Solution Estrone in Oil: 10 cc. vials. A solution in sesame oil containing 1 mg. (10,000 I. U.) of estrogenic activity in each cubic centimeter.

Isoniazid (See New and Nonofficial Remedies 1953, p. 85).

Premo Pharmaceutical Laboratories, Inc., South Hackensack, N. J.

Tablets Nicozide: 50 and 100 mg.

Mephenesin (See New and Nonofficial Remedies 1953, p. 466).

Hexagon Laboratories, Inc., New York.

Powder Mephenesin: Bulk; for manufacturing use.

E. S. Miller Laboratories, Inc., Los Angeles.

Tablets Tolulexin: 0.25 gm.

Mercurophylline Sodium (See New and Nonofficial Remedies 1953, p. 305).

Lincoln Laboratories, Inc., Decatur, Ill.

Solution Mercurophylline (Sodium): 1 cc. and 2 cc. ampuls. A solution containing 0.14 mg. of mercurophylline sodium (equivalent to 39 mg. of mercury) in each cubic centimeter.

Normal Human Plasma-U.S.P. (See New and Nonofficial Remedies 1953, p. 213).

Courtland Laboratories, Los Angeles.

Normal Human Plasma (Lyophilized): 50, 250, and 500 cc. bottles of dried plasma, packaged with an air filter, double-pointed needle and 50, 250, and 500 cc., respectively, of 0.1% citric acid solution for restoration.

Phenindione (See THE JOURNAL, May 9, 1953, p. 142).

Schieffelin & Company, New York.

Tablets Danilone: 50 mg.

Piperazine Estrone Sulfate (See New and Nonofficial Remedies 1953, p. 365).

Abbott Laboratories, North Chicago, Ill.

Elixir Sulestrex Piperazine: 118 cc. bottles. A flavored elixir containing 0.3 mg. of piperazine estrone sulfate in each cubic centimeter.

Pyridoxine Hydrochloride (See New and Nonofficial Remedies 1953, p. 493).

E. S. Miller Laboratories, Inc., Los Angeles.

Tablets Pyridoxine Hydrochloride: 10 mg.

Sulfisoxazole (See New and Nonofficial Remedies 1953, p. 105).

Hoffmann-LaRoche, Inc., Nutley, N. J.

Suspension Gantrisin Pediatric: 118.3 and 473 cc. bottles. A suspension containing 0.1 gm. of sulfisoxazole in each cubic centimeter. Preserved with 0.08% methylparaben and 0.02% propylparaben.

ACUTE RENAL FAILURE

The syndrome of acute renal failure, as seen in crush injuries, was first reported in 1941 by Bywaters and Beall[1] in the *British Medical Journal.* The subject was editorially considered in THE JOURNAL, September 20, 1941.[2] After recovery from the initial shock, in the patients observed oliguria developed, with blood, albumin, and many dark brown and black granular casts. The blood urea and potassium became progressively higher, and death occurred within a week. Necropsies revealed necrosis of the crushed muscle and degenerative changes in the renal tubules. Lauson and his co-workers[3] studied the changes in renal vascular dynamics resulting from peripheral circulatory failure in 35 human cases by means of the clearance methods. Their investigation confirmed the hypothesis that the urinary findings in shock, namely, oliguria and anuria and loss or impairment of concentrating power, are the result of decreased circulation through the kidneys. Oliver and his coworkers[4] demonstrated that the functional and structural alterations in the kidney in the case of acute renal failure caused by toxic or traumatic injuries are those of a tubular nephropathy. The pathogenesis was the same in such clinically different entities as crush injury, transfusion reactions, obstetric accidents, and fatal poisonings. The lesions involved the renal tubules and consisted of disseminated areas of epithelial degeneration, necrosis, and basement membrane rupture.

Swann and Merrill[5] review the literature and their own observations on 100 patients with acute renal failure who have been admitted in the past four years to the Peter Bent Brigham Hospital. The clinical course of this apparently new syndrome is characterized by a period of severe oliguria of a few days' to a few weeks' duration, associated with increasing clinical and chemical evidence of renal failure and followed by a period of rapidly returning function and excretion of water, inorganic ions, and metabolites accumulated during the oliguric period. Oliguria, proteinuria, hematuria, and decreasing urinary specific gravity usually begin within hours of the causative event.

The oliguric phase is followed by the diuretic phase, the period during which clinical improvement and the return of renal function is rapid. Swann and Merrill[5] stress that the transition from the oliguric to the diuretic phase is of major importance in limiting the incidence of the morbidity and mortality from the complications of the oliguric phase. The average duration of oliguria in acute renal failure is about 10 to 12 days. During this phase symptoms and signs are those of cardiovascular, gastrointestinal, and neuromuscular dysfunction. Recognition that after the onset of acute renal failure cardiac function and not the renal function becomes the major concern of the clinician has been according to Swann and Merrill[5] the most important clinical advancement in the past 10 years in the management of this condition. Cardiac dysfunction is the most serious complication of acute renal failure and is the principal cause of death. Two types of cardiac dysfunction are recognized in acute renal failure. The first and commonest form results in pulmonary edema. The second is represented by a cardiac condition associated with hyperkalemia. Pulmonary congestion is a frequent and dangerous complication.

The cerebral complications are those of somnolence, which usually begins toward the end of the first week of oliguria and may progress to stupor, delirium, and coma. Marked delirium and convulsions in the series of Swann and Merrill[5] all appeared to be due to excess administration of water and sodium. Leukocytosis is almost always present early in the oliguric phase. Fever usually follows the initial injury or illness and is present only in the first few days. Rapidly progressing anemia is one of the most constant features of the clinical course. In the oliguric phase, hyponatremia usually occurs with hyperkalemia.

Potassium intoxication is recognized by alterations in the sensorium and by signs of cardiovascular and neuromuscular dysfunction. Cardiovascular signs include faint heart sounds, falling arterial blood pressure, decreasing pulse rate, arrhythmia, periods of asystole, and circulatory collapse. Alterations in the sensorium include anxiety and restlessness progressing to extreme apprehension, sweating, stupor, and terminal convulsions. Neuromuscular signs are those of weakness and hyporeflexia progressing to paralysis of the limbs and of respiration and areflexia, and of paresthesias of the extremities, lips, and tongue, progressing to anesthesia.

Delirium, convulsions, pulmonary edema, vomiting and diarrhea, severe epistaxis, and other manifestations of renal insufficiency may first appear after the onset of the diuresis, even though the daily renal volume exceeds a liter. Patients recovering from acute renal failure show a delayed or blunted response of urinary flow to water intake. A low-grade fever, usually beginning in the second week of the diuretic phase, is characteristic of the course. Marked anemia persists for weeks or months after recovery.

The therapy of acute renal failure has undergone considerable modification because of the recognition that an organic lesion requiring repair is responsible for oliguria. Renal decapsulation and diuretic agents to stimulate urinary flow have been abandoned. Attempts to

induce a greater urinary flow during the oliguric phase may be hazardous. The therapeutic objective is to enable the patient to survive the oliguric period.

A NEW LOOK AT PRICES

Elsewhere in this issue (page 1365) is an analysis from the Bureau of Medical Economic Research of the American Medical Association of the effects on indexes of medical care prices, including fees, of the shifting of the base period from 1935-1939 to 1947-1949, for indexes of consumer prices of the Bureau of Labor Statistics of the United States Department of Labor. The author points out that revisions in the indexes and the addition of approximately 100 commodities and services —such as television sets, frozen foods, and nylons—are genuine improvements. He questions, however, the wisdom of using this new base period, because, for one reason, those three years are an interlude in an inflationary trend that has continued into the 1950's. They do not provide a true base period but rather a temporary foothold on an incline of inflation. The reasons given for shifting to the 1947-1949 period by the Bureau of the Budget, which ordered the change, are not conclusive. Admittedly, it is easier to add new commodities and services to the series by adopting a new base period. In this way, a patchwork of revision is avoided. Nevertheless, in the past items have been added to such series by the "splicing-on process," without changing the base period, even though it may be awkward. One wonders, then, if it is possible that 1947-1949 was chosen by the Bureau of the Budget in order to make the high inflationary levels seem more platable to the consumer. Whatever the reason, or reasons, the choice has made some of the indexes seem somewhat ridiculous.

Because medical prices, among others, such as rents, were relatively static prior to 1949, the shift of the base makes them appear to be superficially high in 1951 and 1952. On the other hand, commodities and services whose prices rose rapidly during the inflationary 1940's, such as women's cotton housedresses, men's street shoes, and haircuts, appear to be relatively low in price in 1951 and 1952 solely because of the shift to the new base period, 1947-1949. Are the prices of women's cotton housedresses, men's street shoes, and haircuts moderate today? A shift in statistical compilation will not convince wage-earners that these commodities and services are low-priced. In 1952 the indexes of medical care prices in general and physicians' fees in particular were below the entire Consumers' Price Index computed on the old base period, 1935-1939. On the new base period, however, they are actually above the Index. This reversal of the relative position of medical care prices in relation to the entire Index will doubtless puzzle many physicians who do not carefully read the article on page 1365.

The least that can be done to restore public confidence in the indexes would be for the Bureau of Labor Statistics to release to the press and the public annual summaries on both the old and the new base periods, at least the sections of the index that go back to 1935-1939. The cost would not be a barrier, for the amount of additional work and mimeographing would be negligible.

Sympathetic understanding of the special problems created by the new base period for some users of the indexes and admonitions by the staff of the Bureau of Labor Statistics for such persons to choose their own base period leaves much to be desired, because Department of Labor publicity offices probably will stress the low indexes for haircuts, women's cotton dresses, and men's shoes. News commentators and the press, not aware of the significance of the change in the index base, will repeatedly state that medical care and rent indexes are higher than the entire Index, that the current rise in the Index was paced by rises in these two items, and that the indexes for women's cotton housedresses, men's street shoes, and haircuts are moderately low.

Those economists who have cooperated with the Commissioner of Labor Statistics and his Washington and regional office staffs in facilitating the gathering of monthly and quarterly data on price changes feel that they have earned the right to object to dropping the old base period completely. The Bureau of Medical Economic Research has repeatedly urged busy physicians to give data on prevailing fees to these field representatives. The Bureau intends to continue to cooperate, because the Consumers' Price Index and its breakdowns are valuable tools for economists. Such cooperation is in the public interest. In turn, the Bureau believes it should insist on the presentation of a set of figures that provide a clearer picture of price relationships for a longer period of time than is possible from the new base period.

If this plea is not to be misunderstood, one further comment seems necessary. The income of physicians is determined by collections and output, as well as by fee schedules; only changes in the fees are reflected in the Consumers' Price Index. The survey of physicians' incomes in 1949, a joint study by the United States Department of Commerce and the Bureau of Economic Research, clearly indicated that the average incomes of physicians and of all gainfully employed persons had been increasing at the same pace. Sample studies indicate that this equality in income increases continued through 1951. A moderate increase in fee schedules combined with a higher percentage of fees collected and a phenomenal increase in "output per physician" has enabled physicians to keep close to the center line of the inflationary highway up which the nation has been traveling so rapidly. In making this request to the Bureau of the Budget and to the Department of Labor, no one is looking for an excuse to claim that physicians' fee schedules should rise during a long inflationary period as rapidly as the entire Consumers' Price Index; there merely is the reasonable request that if they have not risen so rapidly this fact should not be concealed from the public by the exclusive use of the 1947-1949 base period in the revised index after January, 1953.

If the Bureau of Labor Statistics refuses to publish the indexes on the old base period at least once each year, some action seems indicated because of the illusion created by shifting to the new base period. The Director of the Bureau of Medical Economic Research in future articles in The Journal on this subject might well present all indexes on the 1935-1939 base, and other economists may be forced to take a similar position.

ORGANIZATION SECTION

STATEMENT BEFORE HOUSE SUBCOMMITTEE ON HOSPITALS OF THE COMMITTEE ON VETERANS' AFFAIRS

I am Dr. Walter B. Martin of Norfolk, Va., where I am engaged in the active practice of medicine. I am President-Elect and a member of the Board of Trustees of the American Medical Association and am appearing here today (July 13, 1953) as a representative of that Association relative to the hospitalization entitlement of veterans. I am accompanied by Mr. C. Joseph Stetler, Secretary of the Committee on Legislation of the American Medical Association.

At the outset I should like to state that in addition to being a physician I am also a veteran, having served in both World War I and World War II. I can assure you that I am appreciative of the contribution made by men in uniform to their country and the problems, medical and otherwise, which arise during and as a result of their service.

In your letter inviting us to testify certain questions were presented which indicate that the Committee is interested primarily in hospitalization and medical benefits for veterans whose disabilities have no connection with their military service. I shall merely state, therefore, with respect to the care of veterans with service-connected disabilities, that the American Medical Association is and always has been in complete accord with the overwhelming sentiment of the American people that the federal government has a duty to care for any man who has become physically or mentally handicapped as a result of military service.

Inasmuch as your Committee has complete background and statistical information with respect to the eligibility and number of veterans with non-service-conncted disabilities who are receiving hospitalization and medical care, I shall refer to these factors only in general terms. I would, however, like to preface the body of my statement with a brief reference to the history and extent of the interest of organized medicine in this matter.

Since 1925 when the House of Delegates of the American Medical Association registered opposition to the medical provisions of Section 202 of the World War Veterans' Act of 1924, the Association has been in close and constant touch with the medical activities of the Veterans Administration. On more than 30 occasions since that date the House of Delegates and the Board of Trustees have considered various aspects of the program. The most recent action of the Association, which I shall discuss later, was taken by the House of Delegates on June 3 of this year, on the basis of an exhaustive one-year study conducted by a special committee appointed in December, 1951. In accordance with the request contained in your letter of June 22 I have supplied the Clerk of the Committee with sufficient copies of that report to permit complete distribution.

In its deliberations and study of this subject, the Association has worked closely with allied health associations and with major veterans organizations and has considered seriously the views and proposals of each group. Although much discussion has been devoted to the validity of quoted statistics and to the efficiency of the Veterans Administration in the operation of the medical program, it is the belief of the American Medical Association that the really basic questions involved have been ignored.

We feel that the Congress should decide whether existing legislation providing hospitalization and medical care for veterans with non-service-connected disabilities is sound, whether the federal government should continue to engage in a gigantic medical care program in competition with state, local and private medical institutions and whether the ever-increasing cost of such a program is a proper burden to impose on the taxpayers of this country. We further feel that consideration of these problems must be predicated upon a concern for the health and welfare of the entire population and not for just a particular segment.

It is the recommendation of the Association that legislation be enacted limiting medical care and hospitalization benefits for veterans in Veterans Administration and other federal hospitals to the following two categories: (*a*) veterans with peace-time or war-time service whose disabilities or diseases are service-incurred or aggravated; and (*b*) within the limits of existing facilities, to veterans with war-time service suffering from tuberculosis or psychiatric or neurological disorders of non-service-connected origin, who are unable to defray the expenses of necessary hospitalization.

The Association recommends that the provision of medical care and hospitalization in Veterans Administration hospitals for the remaining groups of veterans with non-service-connected disabilities be discontinued and that the responsibility for the care of such veterans revert to the individual and to the community.

The recommendation of the Association with respect to the treatment of veterans with tuberculosis and neuropsychiatric disorders of non-service-connected origin is a temporary one which is believed necessary at this time because of the inadequacy of local facilities designed to provide treatment for all such cases. It is believed, however, that the entire question of whether the care of these patients is a local or federal responsibility must be re-analyzed by the Congress. The rapidly-expanding veterans population and the need for facilities for the remainder of our citizens afflicted with these diseases suggests that community facilities must be developed under state or local administration for the benefit of all. Preferential treatment for veterans with these non-service-connected disabilities cannot be continued indefinitely, in view of the detrimental effect on the health and economy of the entire nation.

Although the initial motivation for the medical program of the Veterans Administration was the desire to provide care for veterans who had become disabled in the course of service to their country, it is now clear that, through congressional acts, administrative interpretations and happenstance, the program has expanded rapidly, primarily during recent years, for the purpose of providing care to veterans whose disabilities have no relationship to military service.

While there may have been sound reasons for originally extending medical care to veterans with non-service-connected disabilities there is considerable doubt that the Congress ever intended that the medical program of the Veterans Administration should develop to its present size. In addition, and of even greater importance, is the obvious fact that if present policies are continued, the federal hospital system devoted to veterans' care will have to undergo considerable further expansion. The ever-increasing number of veterans and the gradual shift in their age distribution to higher age levels with a corresponding increase in chronic disabilities make this expansion inevitable.

It is interesting to note in this connection that there are about 20,000,000 veterans at the present time with an annual increase of approximately 1,000,000. Of this total, approximately 15,000,000 are veterans of World War II, whose average age is about 33 years, compared with 59 years for World War I veterans, and 76 years for Spanish-American War veterans. The Veterans Administration has reported that at the turn of the century there will be almost as many World War II veterans alive (3,404,000) as there are World War I veterans alive today. The average age of the World War II veterans then, however, will be nearly 78.

Before discussing some of the over-all effects of the present medical care program for veterans, I would like to comment on the specific questions presented in your letter of June 22. You inquire particularly concerning contract hospitalization, the establishment of standards for determining eligibility for hospitalization in non-service-connected cases, and whether the possession of health insurance should be a bar to hospitalization in such cases. Although detailed recommendations have not been formulated with respect to all of these questions, I should like to present the general thinking of the Association.

With respect to contract hospitalization, I am sure it is clear from the above that we would be opposed to the use of this medium to extend the present medical program of the Veterans Administration. If, however, such a device could be employed within the framework of our recommendations as outlined above with a resulting more efficient utilization of existing federal and civilian health facilities, we would favor it.

Inasmuch as we have not studied the various administrative methods for determining "inability to pay" I will refrain from making any specific recommendations in this area.

The last point dealing with the admission of veterans with non-service-connected disabilities into Veterans Administration facilities if they are covered by health insurance is one on which we have taken a definite stand. It is our belief that the institution of such a procedure through legislation would, in effect, amount to a standing offer on the part of the federal government to pay part of the cost of hospitalization and medical care for every veteran suffering from a non-service-connected condition. Such a provision could logically be interpreted as permitting the admission of veterans to Veterans Administration facilities irrespective of their financial status, provided that a portion of the cost of such care could be recovered.

At the present time, administrative regulations are in effect in the Veterans Administration which permit the hospitalization of veterans with prepaid health insurance and the collection of the benefits of such policies by the Veterans Administration.

It is our belief that such a practice is a departure from the original theory of the Congress in providing hospitalization for veterans with non-service-connected disabilities. If such a veteran has the ability to pay for his own hospitalization and medical care through insurance or other assets, it was not intended that he be admitted to a Veterans Administration hospital.

Any complete consideration of the potentialities of the Veterans Administration medical program necessitates a recognition of medical manpower problems, in general, and of the combined effect of the various governmental medical programs on the health of the nation.

Of all of the many important problems that exist in this period of limited mobilization there is none more difficult of analysis and final solution than that of manpower. While it is true that today we have more physicians per thousand population than any other major country and that the productivity of the individual practitioner is constantly increasing, nevertheless the medical manpower situation will be rendered critical if the present rapid uncoordinated expansion of government medical services is allowed to continue.

As the federal government siphons off the medical and allied health personnel needed to meet its continually expanding requirements, the talent available for the civilian population diminishes. This creates an artificial shortage of doctors and other health personnel for the rest of the population. As a result, we continually hear that a shortage of doctors exists. Yet in 1940, before the war, no one maintained that there was such a shortage. In fact, there was a shortage of patients. Many young and well-trained doctors were finding it difficult to establish practices. In 1940 there were 169,628 physicians in the United States. By 1952 the number had increased to 216,200, a gain of 46,572. Thus, although the population of the country had increased by 20 per cent the physician population had increased by 28 per cent.

With respect to the impact of the medical program of the Veterans Administration on civilian health facilities, it should also be noted that this country has developed a large voluntary hospital medical training program that centers around the medical schools and voluntary teaching hospitals. This system is partly supported through the Hill-Burton Act and by various grants to medical schools for research. In addition, however, the federal government maintains five major medical training activities for interns and residents under the Veterans Administration, the Army, Navy, Air Force and the United States Public Health Service. These medical services were designed originally to meet the needs of certain groups. However, their activities have been gradually expanded by drawing into their sphere a constantly increasing number of civilians who previously were cared for by private civilian medicine. Where formerly these services relied on civilian training programs to provide skilled specialists, they have now embarked on training programs of their own. In order to qualify for resident and intern training, it is necessary for service hospitals to provide diversified clinical material. As a consequence there has been increasing pressure to draw into theses hospitals non-service-connected general medical and surgical cases from among the veteran population as well as dependents of service personnel.

As a result, government hospitals are in competition with civilian hospitals not only for personnel but also for patients. Although the federal government, aided by state and local subdivisions, is spending millions of dollars under the Hill-Burton Act in civilian hospital construction it is becoming increasingly dfficult for them to operate at a reasonable cost because patients and health personnel are being diverted into hospitals wholly supported by the federal government. This policy is producing a wasteful duplication of hospital facilities and an unwarranted dispersion of health personnel which not only threatens our great voluntary civilian teaching program but causes a continual increase in the cost of hospital and medical care for persons who must pay their own way.

In its testimony before Congress, and at other times, the American Medical Association has repeatedly pointed out the wastefulness inherent in the present uncoordinated system for providing medical care and hospital benefits by the federal government. The House of Delegates and the Board of Trustees of the Association have, on several occasions, reiterated the belief that one of the ways to institute governmental economy in the use of funds and medical manpower is to establish a Federal Board to allocate the number of beds required by the several federal hospital services; to insurance joint planning in the field of civilian and federal hospital construction; and to determine the need for and location of proposed new hospitals in the United States.

In summation, I would like to say that in arriving at its recommendations in the field of veterans' medical care, the American Medical Association has made an earnest effort to properly respect and have a sympathetic concern for all interests involved. Some will point out that the hospital casts of indigent veterans with non-service-connected conditions will be the taxpayer's responsibility in any event, either through the use of state or federal funds.

We believe that a careful review of the facts will prove that the wisest eventual course will dictate that responsibility for the care of veterans with disabilities having no relationship to military service should revert to the individual and to the state and local communities where it rightfully belongs.

The gradual expansion and intervention of the federal government into the affairs of local governments and individuals during the past decade has apparently confused some people as to the proper responsibilities of each. Continued federal encroachment into private affairs cannot be advocated logically and consistently by those who, at the same time, voice their opposition to socialism. It is time to reorient our thinking and to recognize the dangers which threaten the foundation of our basic philosophy before we reach the point of no return in terms of collective socialistic planning. It would be unfortunate indeed, if, in our efforts to reward patriotism, we were responsible for the creation of a system of government medicine, against the will of the majority, with its inevitable deterioration in the quality of medical care for veterans and non-veterans alike.

The American Medical Association discerns in this situation a urgent present need for a courageous stand and for the formalization of a legislative program limiting the activities of the federal government in the field of veterans' medical care. This is a most propitious time for creative legislative thinking and action in the solution of the important problems involved.

In conclusion, I would like to stress again the fact that the recommendations which we have made do not suggest any limitation or impairment of the hospitalization or medical care now available to veterans who have become handicapped as a result of military service. We are in complete accord with that program.

I would also like to thank the Committee on my own behalf and on behalf of the American Medical Association for the opportunity to present our views and recommendations on this extremely important subject.

CLINICAL MEETING, ST. LOUIS, DEC. 1-4, 1953

Dr. Llewellyn Sale, chairman of the Local Committee on Arrangements for the Clinical Meeting of the American Medical Association in St. Louis, Dec. 1-4, 1953, announces that plans are developing rapidly and that from all indications the meeting will be an outstanding one. All scientific activities will be held in Kiel Auditorium, where there are ample facilities for the lecture program, Scientific Exhibit, Technical Exposition, motion picture program, and television. The House of Delegates will hold its sessions at the Jefferson Hotel.

Dr. Daniel L. Sexton, subchairman in charge of clinical presentations, has nearly completed the program for clinical presentations and color television. These will cover the fields of medicine, surgery, pediatrics, obstetrics and gynecology, tuberculosis and other diseases of the chest, cardiovascular diseases, arthritis, dermatology, gastrointestinal diseases, and neuropsychiatry. Arrangements for color television to be presented through the cooperation of Smith, Kline and French Laboratories, have been completed, but the showing of this program at the meeting will depend on the settlement of a jurisdictional dispute between two labor unions in the auditorium.

The Scientific Exhibit will be correlated as far as possible with the clinical presentations. Besides a group of 75 or 80 exhibits on the above subjects, there will be several special features. The special exhibit on fractures will be shown as usual under the fracture exhibit committee, composed of Dr. Gordon M. Morrison, Boston, chairman; Dr. Ralph G. Carothers, Cincinnati, and Dr. Herbert Virgin Jr., Miami, Fla.

A contemplated feature is an exhibit symposium on the prevention of traffic accidents. This would include the responsibility of the physician in telling his patient when he should not drive and what other precautions he should take in special situations, the testing of the drinking driver, precautions to be taken by automobile manufacturers in the reduction of hazards, and the care of the injured after an accident. Cooperation of the various agencies interested in the problem will be discussed, such as the National Safety Council, the traffic division of the police, and the various medical groups that have been attempting to solve this problem.

Medical motion pictures will be shown continuously, with the authors present, whenever possible, to discuss their work. The Committee on Medical Motion Pictures is arranging the program. The Council on Scientific Assembly is in charge of the clinical presentations and color television, while the Committee on Scientific Exhibit is in charge of the scientific exhibit and motion pictures. Applications for space in the Scientific Exhibit may be obtained from the Director, Scientific Exhibit, American Medical Association, 535 N. Dearborn St., Chicago 10, Ill.

IMPOSTOR SOUGHT

Information is urgently needed concerning the whereabouts of an alleged physician who uses the name Dr. Samuel Pike Hall. Anyone knowing his present whereabouts should contact by wire Mr. Charles R. Vaughan, State's Attorney of Richland County, Olney, Ill. The man in question is described as follows: height, 5 ft. 10½ in.; weight, 180 lb.; hair, black; age, 39; eyes, brown; complexion, dark. He has a scar on the right side of his chest. He is reported to have left Olney, Ill., where he posed as a physician, abandoning his pregnant wife without support, and owing sums of money. While in Olney, he is alleged to have conducted himself as a physician in such a manner as to gain admiration from his professional associates.

The Journal published notification of this impostor on Aug. 14, 1948, page 1475. As pointed out there, this man is not to be confused with Dr. Samuel Pike Hall of Oakland, Calif., or Dr. Samuel Parks Hall Jr., of Scottsboro, Ala., both of whom are reputable physicians engaged in the practice of medicine in their respective communities.

FEDERAL MEDICAL LEGISLATION

Public Assistance

Senators Sparkman and Hill, Democrats from Alabama, propose in S. 2351 to authorize for an additional two years after September, 1954, the present rate of federal contribution to the states for assistance for dependent children and the aged, blind, and disabled. The bill is identical with S. 1933, introduced by Senator Humphrey and previously reported. This bill was referred to the Finance Committee.

Voluntary Pension Plans

Congressman Elliott (D., Ala.) introduced H. R. 6114 to permit tax deduction in calculating income tax to facilitate the creation of retirement annuities by the self-employed. This measure is identical with H. R. 10 (Jenkins) and H. R. 11 (Keogh), previously reported. This measure was referred to the Ways and Means Committee.

Retirement Benefits for Disabled

Congressman Fino (R., N. Y.) proposes in H. R. 6115 "to amend the Social Security Act to provide that (for the purpose of old-age and survivors insurance benefits) any insured individual who is totally and permanently disabled, and who has not less than twenty quarters (five years) of coverage, shall be deemed to have reached retirement age." A "totally and permanently disabled individual" is defined as "unable to engage in any substantially gainful activity by reason of any medically determinable physical or mental impairment which is permanent in nature, or . . . blind." The bill does not specify how disability would be determined, hence the Secretary of Health, Education, and Welfare under existing authority would issue regulations regarding such determinations. This bill was referred to the Ways and Means Committee.

College Scholarship Funds

Congressman Lane (D., Mass.) proposes in H. R. 6124 to establish a federal scholarship revolving loan fund, with the states contributing up to 10% of the amount advanced to its borrowers. State loans could be made only to students accepted by an educational institution. The states would furnish lists of eligible applicants to the U. S. Commissioner of Education. This measure is similar to H. R. 6079 (Boland), previously reported. Both bills were referred to the Committee on Education and Labor.

Old-Age and Survivors Insurance

A series of identical bills were introduced to broadly revise the old-age and survivors insurance system. In the House of Representatives these bills are H. R. 6128 (Perkins, D., Ky.), H. R. 6162 (Dollinger, D., N. Y.), H. R. 6163 (Fine, D., N. Y.), H. R. 6164 (Klein, D., N. Y.), H. R. 6175 (Buckley, D., N. Y.), H. R. 6180 (Rodino, D., N. J.), H. R. 6215 (Addonizio, D., N. J.), and H. R. 6229 (Metcalf, D., Mont.). These bills are identical with S. 2260, introduced by Senator Lehman of New York and 10 other Senators, and identical with 11 House bills previously reported. The major revisions (1) extend the coverage to a large group of professional and nonprofessional workers (not including physicians or dentists); (2) increase the portion of income subject to taxation; (3) increase the monthly dollar benefits; (4) increase the amount a retired person may earn from $75 to $100 per month without forfeiture of benefits; (5) provide benefits for the permanently and totally disabled; and (6) establish cash sickness benefits. These bills were referred to the Ways and Means Committee.

The summary of federal legislation was prepared by the Washington Office of the American Medical Association and the summary of state legislation by the Bureau of Legal Medicine and Legislation.

STATE MEDICAL LEGISLATION

California

Bills Enacted.—A. 1378, has become ch. 1800 of the laws of 1953. It amends the Business and Professions Code by providing that **examinations for the physician's and surgeon's certificate** may be conducted by the board under a uniform system and for that purpose the board may make such arrangements with the organizations furnishing examination material as may in its discretion be desirable. S. 1970, has become ch. 1385 of the laws of 1953. It adds to the penal code regulations for the creation within the department of justice of a **bureau of criminal identification and investigation.**

Connecticut

Bills Enacted.—H. 407, has become public act no. 1350 of the acts of 1953. It authorizes the conducting of **postmortem examinations and autopsies** upon a written consent given by telegram and any telegram purporting to have been sent by a person authorized to give such consent shall be conclusively presumed to have been sent by such person. H. 435, has become public act no. 189 of the acts of 1953. It amends the medical practice act by, among other things, authorizing the Connecticut medical examining board, in its discretion and subject to such regulations as the board may prescribe, to issue permits to persons otherwise licensed to practice medicine in the state except that they do not meet the residence or citizenship requirements for such license or are graduates of foreign medical schools not accredited in Connecticut to serve as **interns or residents in hospitals in the state for the purpose of extending their education.**

Delaware

Bills Enacted.—H. 387, was approved July 1, 1953. It requires every physician attending or treating **epilepsy** to report such cases to the department of motor vehicles. H. 392, was approved July 1, 1953. It requires every physician attending or treating a case of **bullet wounds, gunshot wounds, powder burn, or other injury arising from or caused by the discharge of a gun, pistol, or other firearm,** or whenever such case is treated in a hospital, sanitarium, or other institution, the manager, superintendent, or other person in charge shall report such case at once to the police authorities.

Hawaii

Bills Enacted.—H. R. 19, was adopted March 12, 1953. It resolves that the directors of all public and private hospitals be encouraged to furnish adequate **dental facilities** at their respective hospitals so that they can promote public health and welfare for the people of the territory. H. 324, was approved April 22, 1953. It amends the law relating to **narcotic drugs** by, among other things, making it the duty of **every attending or consulting physician to report** to the board of health promptly the names of persons under treatment if it appears that such persons are habitual users of narcotic drugs.

Illinois

Bills Enacted.—H. R. 34, was adopted Feb. 17, 1953. It provides for the creation of a committee to investigate the need for and the desire to have a **state institution for narcotic addicts.** H. 988, was approved June 30, 1953. It provides for the construction, equipment, and operation of a **psychiatric institute state hospital** to promote and advance knowledge through research in the causes and treatment of mental illnesses, to train competent psychiatric personnel available for service in the state hospitals and elsewhere, and to contribute to meeting the need for treatment for mentally ill patients. S. 347, was approved July 6, 1953. It is a **rabies** control act. S. 412, was approved July 1, 1953. It is a **hospital licensing law.** S. 417, was approved July 1, 1953. It amends the administrative code by authorizing the department of public health to establish and enforce **minimum standards for the operation of all general hospitals.** S. 422, was approved July 7, 1953. It amends the law relating to the practice of chiropody by **defining chiropody** as the diagnosis, medical, physical, or surgical treatment of the ailments of the human foot, with the exception of administration of general anesthetics or amputation of the foot.

Massachusetts

Bill Enacted.—H. 767, has become resolution ch. 16 of the laws of 1953. It provides for the appointment of a special commission to investigate and study relative to the care, treatment, and commitment of the **criminally insane and defective delinquents.**

Michigan

Bill Enacted.—H. R. 36, was adopted May 15, 1953. It provides for the creation of a special committee to study the laws relating to **admission to mental hospitals.**

Missouri

Bills Enacted.—H. 355, was approved July 10, 1953. It repeals existing law and enacts a new law in lieu thereof relating to the hospitalization of the **mentally ill.** S. 422, was approved June 29, 1953. It is a **hospital licensing law.**

Oklahoma

Bills Enacted.—H. 846, was approved June 3, 1953. It is a **mental health law.** S. 325, was approved June 8, 1953. It is a licensing law for the regulation of **rest homes, nursing homes and related institutions.**

Pennsylvania

Bills Introduced.—H. 1562, to amend the vital statistics law, proposes to authorize the execution of the **medical certification on the death certificate by a chiropractor** who attended the deceased during his last illness. H. 1606, to amend the law relating to mental health, proposes that no officer or employee of the department of mental health, including hospital personnel, shall be held liable personally for his official conduct of the care of a patient in any action commenced by or on behalf of such patient alleging **malpractice, libel, or negligence,** unless such action sets forth facts showing conduct (1) beyond the scope and powers of such officer or employee under this act or (2) less than or beyond the usual or customary practice of caring for a patient of such type at the time of the conduct complained of. S. 757, proposes to make it a misdemeanor to fraudulently obtain **gamma globulin** from the department of health or any of its agents.

Texas

Bills Enacted.—H. 71, was approved June 8, 1953. It amends the **narcotic drug act** by, among other things, **providing penalties for sales to minors,** by adding amidone and isonipecaine and every substance neither chemically or physically distinguishable from them together with drugs found to be addiction-forming or addiction-sustaining in a manner similar to opium or cocaine to the list of narcotic drugs and by defining a licensed physician as a person duly licensed by the Texas board of medical examiners. H. 254, was approved June 13, 1953. It amends the medical practice act by, among other things, providing a penalty for failure of a licentiate to pay his **annual registration fee** whether such licentiate practices within the border of the state or not. H. 353, was approved June 8, 1953. It provides certain amendments to the **naturopathic practice act** by, among other things, terminating the grandfather clause contained in the 1949 law. H. 415, was approved May 27, 1953. It provides that consent for licensed physician to **conduct an autopsy on the body of a deceased person** shall be deemed sufficient when given by the following: in the case of a married person, the surviving spouse or if no surviving spouse by a child of such marriage, or in the event of a minor child of such marriage by the guardian, or in the absence of such guardian by the court having jurisdiction of the minor. If the deceased be unmarried it shall be given by the following: father, mother, guardian or next-of-kin or in the absence of any of the foregoing by any natural person assuming custody of and responsibility for burial, of the body. H. 559, was approved June 9, 1953. It provides for the creation of a **commission on alcoholism** to carry on a continuing study of the problems surrounding alcoholism in the state, to establish cooperative relationships with state agencies, hospitals, clinics, etc., to promote or conduct educational programs on alcoholism, to establish local alcohol clinics, etc. S. 303, was approved June 4, 1953. It provides for the creation of **county-wide hospital districts** in certain counties.

Wisconsin

Bills Enacted.—A. 238, has become ch. 411 of the laws of 1953. It provides for the issuance of licenses to practice **physical therapy** by the board of medical examiners and defines the practice of physical therapy as the treatment of disease by the use of physical, chemical and other properties of heat, cold, light, water, electricity, massage, and therapeutic exercises including posture and rehabilitation procedures, but the use of roentgen rays and radium for any purpose and the use of electricity for surgical purposes including cauterization are not included in the practice of physical therapy. The only persons who are permitted to use the term "Physical Therapist" or the initials "P. T." or similar initials indicating that they are physical therapists are those who have been issued a license by the board of medical examiners or those who are practicing under a prescription and the direct supervision of a person licensed to practice medicine and surgery. The law does not prohibit any person licensed or registered in this state under another law from engaging in the practice for which he is licensed or registered. A. 334, has become ch. 391 of the laws of 1953. It amends the law relating to **dangerous drugs** by providing that an oral prescription by telephone or otherwise for a dangerous drug shall promptly be reduced to writing and filed by the pharmacist. S. 133, has become ch. 459 of the laws of 1953. It amends the law relating to **expert testimony** by providing that no person without a license or certificate of registration from the state board of medical examiners shall have the right to testify in a professional capacity on a subject relating to medical treatment as a medical or osteopathic physician or practitioner of any other form or system of treating the sick, providing that a medical or osteopathic physician licensed to practice in another state may testify as the attending or examining physician or surgeon to the care, treatment, examination, or condition of sick or injured persons whom he has treated in the ordinary course of his professional practice for the sickness or injury which is the subject of the judicial inquiry in any action or proceeding in which he is called as a witness. Nonresident witnesses, however, shall not be permitted to testify as attending or examining physician or surgeon or as expert witness on a medical subject unless the party calling such witness has served on the opposing party a five day written notice in advance of calling such witness to testify stating the name of such witness, his residence, and business address. S. 160, has become ch. 342 of the laws of 1953. It amends the **medical practice act** by, among other things, eliminating the list of subjects in which applicants must be examined and substituting therefor the requirement that applicants must be examined in "medicine and surgery"; and also by adding to the definition of immoral or unprofessional conduct "engaging in conduct unbecoming a person licensed to practice or detrimental to the best interests of the public." S. 161, has become ch. 405 of the laws of 1953. It authorizes the board of **basic science examiners** to accept either in whole or in part the certificate of the national board of medical examiners provided that certification by the national board is accepted by the state board of medical examiners in whole or in part and has been accepted by the basic science boards of at least six other states.

MEDICAL NEWS

ARKANSAS

Medical Fund Named for Dr. Norwood.—In recognition of service rendered the Arkansas Medical Society by Dr. Merrieman L. Norwood of Lockesburg, a fund to provide for the study of medicine by state boys and girls will be known as the Norwood Fund. Dr. Norwood originated the plan to provide funds for medical study to state high school graduates needing financial assistance, who agree to return, after graduation, to some town of less than 2,000 population and remain five years.

CALIFORNIA

Dr. Goodhart Appointed Dean.—Dr. Gordon E. Goodhart, Los Angeles, who has been on the faculty of the University of Southern California School of Medicine for five years, has been named to succeed Dr. Burrell O. Raulston, dean for 10 years and on the faculty since 1929, who will become dean emeritus. Dr. Raulston was given an honorary degree of doctor of science by Southern California at its 70th annual commencement exercises June 13 "in recognition of distinguished service in the field of medicine." Dr. Goodhart was formerly director of medical extension education for the school and for the past year served as associate dean. He became affiliated with the Los Angeles County Hospital as a resident physician after World War II service as a captain in the Army Medical Corps in Europe, and became chief of the outpatient service for the County Hospital in 1948 and coordinator of its resident training program the next year.

Personal.—Dr. Ernest H. Falconer, clinical professor of medicine, University of California Medical School, San Francisco, and since 1921 chief of the blood clinic, University of California Hospital, was recently honored by his alma mater, McGill University, Montreal, Canada, which bestowed on him the degree of doctor of laws.——Dr. Richard Thomas Barton, instructor in surgery, University of Southern California School of Medicine, Los Angeles, addressed the Fifth International Congress of Otolaryngology on June 12 in Amsterdam, Netherlands. He spoke on neoplasms involving the carotid artery.——Dr. Bertram V. A. Low-Beer, professor of radiology in the University of California Medical School, Berkeley-San Francisco, recently delivered a paper on "The Internal and External Use of Radiophosphorus" at the Seventh International Congress of Radiology in Copenhagen, Denmark.——Dr. Milton V. Veldee, Los Angeles, is serving as a consultant to the Stanford Research Institute of Palo Alto and to the Michael Reese Research Foundation of Chicago. Dr. Veldee, formerly a medical director in the U. S. Public Health Service and chief of the Laboratory of Biologics Control, has resigned as vice-president and medical director of the Hyland Laboratories of Los Angeles.

CONNECTICUT

Who Pays the Hospital?—A study recently completed by the Connecticut Hospital Association, including analysis of cases and patient days in the 34 general hospitals in the state for the 12 months ended Sept. 30, 1952, shows that only 15% of patient days in Connecticut's community hospitals were paid for by the patients. Connecticut Hospital Service (Blue Cross) absorbed the costs of 50% of cases and 45.5% of patient days. Commercial insurance carriers paid 24.5% of total hospital charges in both categories, and city and town welfare budgets were called on to meet costs for only 1.5% of cases and 2.5% of patient days.

ILLINOIS

Unauthorized Cancer Fund Solicitations.—The Illinois Division of the American Cancer Society announces that it has not authorized use of its name in connection with a newspaper subscription campaign raising funds for "cancer." Professional solicitors, who promise a contribution to a "cancer fund" in return for a newspaper subscription, have been calling Chicago and suburban residents to say that the "cancer drive" has failed to reach its goal. On the contrary, the division reports, the Cancer Crusade has actually exceeded its goal and has ended as one of the most successful in history.

Chicago

Dr. Manlove Goes to Colorado.—Dr. Francis R. Manlove, associate secretary of the A. M. A. Council on Medical Education and Hospitals, has been appointed director of the University of Colorado Medical Center in Denver, dean of the department of medicine, and professor of medicine, to succeed Dr. Ward Darley, who became president of the university July 1. Until Dr. Manlove takes up his new duties shortly after Oct. 15, Dr. Robert C. Lewis, dean of the medical school, will continue as acting director of the medical center. Dr. Manlove was previously affiliated with the Mayo Foundation for Medical Education and Research, the Mayo Clinic, Rochester, Minn., and Temple University School of Medicine in Philadelphia. He is an adviser to the director of the Selective Service System and a member of several national committees on medical education.

University News.—Dr. Tibor Benedek has been appointed assistant professor of dermatology in Stritch School of Medicine of Loyola University. During World War II he was chief of the dermatological service at Fletcher General Hospital, Cambridge, Ohio, and later at the 233rd General Hospital in the Asiatic Pacific Theater.——The following appointments to the faculty of the Chicago Medical School have been announced: Dr. Irving J. Shapiro, associate professor of urology; Dr. Herman M. Soloway, associate professor of clinical genitourinary surgery; Dr. Louis Edidin, assistant professor of clinical medicine; Dr. William F. Lichtman, assistant in orthopedic surgery; Dr. Marvin Padorr, assistant in pediatrics; and Dr. Samuel Nien-Tsu Wong, instructor in surgery.——At the commencement exercises of the Chicago professional colleges of the University of Illinois, June 18, emeritus status was awarded to the following faculty members who will retire Sept. 1: Dr. Thomas Cottrell, clinical assistant professor of urology; Dr. Michael H. Ebert, clinical professor of dermatology; Drs. Georgiana Theobald and Earle B. Fowler, clinical associate professors of ophthalmology; and Dr. Sidney A. Portis, who recently resigned as clinical associate professor of medicine to enter private practice in California.

IOWA

Dr. Steindler Honored.—Dr. Arthur Steindler, head of the department of orthopedics at Mercy Hospital, Iowa City, has been made an honorary member of the British Orthopedic Association "on the basis of his outstanding contributions to orthopedic surgery in regard to the basic studies of orthopedic problems and for his major contributions of many orthopedic textbooks and articles and in particular for his outstanding efforts in training and teaching." For more than 30 years Dr. Steindler served as head of the orthopedic department of the State University of Iowa College of Medicine in Iowa City.

KANSAS

Dr. Jury Honored.—Dr. Herbert W. Jury, who at the age of 78 is still practicing after 50 years of service, was recently feted by more than 2,000 residents of Claflin and surrounding communities. Members of the Methodist WSCS, Lutheran Ladies'

Physicians are invited to send to this department items of news of general interest, for example, those relating to society activities, new hospitals, education and public health. Programs should be received at least three weeks before the date of meeting.

Aid, Southern Baptist Women, and the Altar Society of the Immaculate Conception Catholic Church collected 50 silver dollars, which were hung from a gold-trimmed money tree, which they presented to Dr. Jury. He had previously been honored by the Claflin Lions Club and by the physicians of Hoisington, Ellinwood, and Great Bend.

MARYLAND

Dr. Reed Retires as Hopkins Vice-President.—Lowell J. Reed, Ph.D., vice-president of the Johns Hopkins University and Hospital and since 1949 administrative head and coordinator of all Hopkins medical activities, retired as of June 30 after 35 years as a member of the faculty and administrator. The responsibilities formerly discharged by Dr. Reed as vice-president have been assigned to the medical planning and development committee, consisting of the deans of the schools of medicine and of hygiene and public health and the director of Johns Hopkins Hospital. Dr. Reed, who has been appointed professor emeritus of biostatistics, will assist the Johns Hopkins institutions in bringing to fruition certain long-range plans, in the formulation of which he has played an important part. Dr. Reed, together with the late Raymond Pearl, Ph.D., whom he succeeded as professor of biostatistics in 1925, wrote the mathematical formula for the logistic curve as related to the growth of populations, which led to the development of epidemic theory, an explanation of the varying cycles of contagious disease in a community. Dr. Reed was a member of the President's Commission on the State of the Nation's Health and since the outbreak of World War II has been consultant on Manpower and Medical Statistics to the surgeons general of the Army, Navy, and Air Force, U. S. Public Health Service and Selective Service, U. S. State Department, National Research Council, the Veterans Administration, and a member of the National Advisory Health Council. For many years he has been a consultant and member of scientific boards of the Rockefeller Foundation, the Commonwealth Fund, and the Milbank Memorial Fund. In 1943 he was chairman of the United States delegation to the Inter-American Demographic Conference in Mexico City; in 1947 he headed the U. S. Committee on Joint Causes of Death, which won the Lasker Award in Public Health for its work on the International List on Morbidity and Mortality; and in 1948 he was named chairman of the Surgeon General's Committee on Medical School Grants and Finances. Dr. Reed was dean and director of the Johns Hopkins School of Hygiene and Public Health from 1937 to 1946, when he was appointed vice-president of the university in charge of medical activities. In 1949 he was named vice-president of the hospital, the first such dual appointment in the history of the university.

MASSACHUSETTS

Dr. Paul Patterson Goes to Albany.—Dr. Paul R. Patterson, instructor in pediatrics, Harvard Medical School, Boston, has been appointed professor of pediatrics, Albany (N. Y.) Medical College, and pediatrician-in-chief to the Albany Hospital. Dr. Patterson, who has been affiliated with the Kansas City (Mo.) General Hospital, the Research and Educational Hospitals of the University of Illinois, and the University of Illinois College of Medicine, Chicago, has served as director of the diagnostic laboratory at the Children's Medical Center, Boston.

Society News.—At the annual dinner-meeting of the Massachusetts Society of Examining Physicians at the Harvard Club in Boston, the following officers were elected: president, Dr. Charles H. Bradford, Boston, president-elect, Dr. Carl Bearse, Boston, vice-president, Dr. Ronald W. Adams, Boston, treasurer, Dr. Robert C. Gwin, Brookline, and secretary, Dr. J. Robertson Knowles, Boston.——At its annual meeting in Boston the Massachusetts Medical Society elected Dr. Frederic Hagler, Springfield, president, Dr. Curtis C. Tripp, New Bedford, president-elect, and Dr. Harvey A. Kelley, Winthrop, vice-president. Dr. Robert W. Buck, Boston, who was serving as secretary pro tem, was made secretary, and Dr. Eliot Hubbard Jr., Cambridge, was reelected treasurer.

MICHIGAN

Dr. De Jongh Wins Industrial Award.—At its recent convention in Los Angeles the Industrial Medical Association named Dr. Edwin De Jongh, medical director of the Detroit Diesel Engine Division of General Motors, as winner of the meritorious service award. Dr. De Jongh, who designed a surgical tray to be used in emergencies, was honored "for making the greatest contribution to the association."

Dr. Burley Week.—"In recognition of the splendid service to the community and the untiring efforts on behalf of its citizens and for the 60 years of service to humanity," the village president of Almont proclaimed a "Dr. Burley Week," in which the community honored Dr. David H. Burley, 89, a life member of the Michigan State Medical Society. The week of recognition started with a special service at the First Congregational Church on Sunday and ended with a potluck picnic at the school grounds on Friday, when the community's gift, a fund to help establish a 50 bed hospital, was announced.

MINNESOTA

Wangensteen Surgical Foundation Established.—The Owen H. Wangensteen Surgical Education Foundation has been established at the University of Minnesota, Minneapolis, to promote advanced surgical education. Initial funds were donated by Dr. F. John Lewis, associate professor of surgery, Dr. Richard L. Varco, professor of surgery, and Dr. Charles E. Rea, clinical associate professor of surgery. Dr. Wangensteen will act as an adviser in administration of the funds.

Personal.—Drs. William C. Mussey and Joseph B. Seagle, recently attached to the Mayo Clinic staff at Rochester, Minn., have joined the staff of Carle Memorial Hospital in Urbana, Ill. ——On a recent visit to Santiago, Chile, Dr. Thomas B. Magath of Rochester was made an honorary member of the Medical Faculty of the University of Chile in recognition of his contributions to the field of parasitology.——Dr. Donald C. Balfour, professor of surgery, University of Minnesota Graduate School, Rochester, has been elected foreign correspondent in the second division (surgery, obstetrics, and surgical specialties) by the National Academy of Medicine of France.

NEW JERSEY

Dr. Eckardt Accepts University Appointment.—Dr. Robert E. Eckardt, Linden, has been appointed an associate clinical professor of industrial medicine at the New York University College of Medicine. Dr. Eckardt is director of the medical research division of the Standard Oil Development Company.

Dr. Murn Honored.—Dr. Charles J. Murn, Paterson, a past president of the Passaic County Medical Society, was honored by Fordham University, New York, in a ceremony that paid tribute to its three oldest graduates. Dr. Murn, who graduated in the class of 1903 and has served as Paterson's health commissioner, jury commissioner, and as president of St. Joseph Hospital for many years, was congratulated by Cardinal Spellman on his years of achievement and service.

Cancer Fellowships.—The New Jersey State Department of Health announces several fellowships for residency training in oncology. Each fellowship, for one full year of training, will be granted in general oncology or in one of the special aspects of this subject; stipend is $3,600 per year. Applicants must be citizens of the United States, licensed to practice in the state of New Jersey or eligible for licensure, and must have been accepted by one of the participating institutions: Elizabeth General Hospital and Dispensary and James S. Green Memorial Tumor Clinic, Elizabeth; Memorial Center for Cancer and Allied Diseases, New York; American Oncologic Hospital and Jeanes Hospital, Philadelphia. Information and application forms may be obtained from the New Jersey State Department of Health, Bureau of Cancer Control, 65 Prospect St., Trenton.

NEW YORK

Trudeau Meeting.—The Trudeau School of Tuberculosis announces that at its recent four week course at Trudeau Sanatorium and Saranac Lake, the best attended in its 39 year history, physicians came from 11 states and 12 foreign countries: Pakistan, Thailand, Canada, Japan, China, Germany, Paraguay, India, Brazil, the Philippines, El Salvador, and Turkey. They included public health officers, staff physicians of hospitals and clinics, instructors, and physicians from the armed services.

Dr. Ingraham Named First Deputy.—Dr. Hollis S. Ingraham, Albany, who has been affiliated with the state department of health since 1934 and has served as a deputy commissioner since Aug. 1, 1948, has been appointed first deputy health commissioner, succeeding Dr. William A. Brumfield, who resigned to become professor of public health and preventive medicine at the State University of New York College of Medicine at Syracuse. Dr. Ingraham, who served during World War II as a lieutenant commander in the Navy, also saw overseas service with the U. S. Typhus Commission at Cairo, Egypt.

New York City

Increased Incidence of Tuberculosis.—According to the annual report of the New York Tuberculosis and Health Association, although the death rate from tuberculosis shows a marked decline, the incidence of new tuberculosis cases in New York City continues to rise. In the first three months of 1953, as compared with same period in 1952, new cases throughout the city increased 5% and were discovered in an advanced stage, making the cure longer and more expensive. There are presently 18,319 cases of active tuberculosis in the five boroughs. As of March 31, only half of Manhattan's 8,391 tuberculosis patients were receiving hospital care.

March of Dimes Grants.—Grants totaling $47,994 were recently received by the New York University-Bellevue Medical Center from the National Foundation for Infantile Paralysis. A grant of $15,594 will enable medical center scientists, under the direction of Mark H. Adams, Ph.D., associate professor of microbiology at New York University College of Medicine, to continue their fundamental studies and obtain further knowledge of the nutritional requirements of viruses as they multiply at the expense of the host cells. Dr. Adams' group, which previously demonstrated that certain bacterial viruses will not multiply in host cells unless fairly high concentrations of calcium are present, will now study the effect on virus multiplication of varying calcium concentrations in an effort to pinpoint the calcium dependent stage. They will also study the problem of developing mutant or hybrid virus types by reshuffling the genes that control inherited characteristics. Under the direction of Dr. Currier McEwen, dean of New York University College of Medicine, and Dr. Howard A. Rusk, chairman of the department of physical medicine and rehabilitation, $9,720 will be used toward teaching the basic concept and techniques of medical rehabilitation to medical students. An additional grant in the amount of $22,680 will enable New York University College of Medicine to expand a specialized training program in physical medicine and rehabilitation, for better care of patients handicapped by poliomyelitis and other crippling diseases.

NORTH CAROLINA

Society News.—At its annual meeting in Pinehurst the Medical Society of the State of North Carolina elected the following officers: president, Dr. Joseph A. Elliott Sr., Charlotte; president-elect, Dr. Zack D. Owens, Elizabeth City; vice-presidents, Drs. John F. Foster, Sanford, and Julian A. Moore, Asheville. Dr. Millard D. Hill, Raleigh, continues as constitutional secretary and Mr. James T. Barnes, Raleigh, as executive secretary.

Dr. Forbus Goes to Formosa.—Dr. Wiley D. Forbus, chairman of the pathology department, Duke University School of Medicine, Durham, has been granted a leave of absence to accept a six month assignment as a Mutual Security Agency consultant in Formosa. His primary task will be to assist in the rehabilitation of the National Taiwan University Medical School, Taipeh, Taiwan. This program will include setting up teaching residencies and residency training programs, as well as establishing diagnostic laboratories in the hospital and medical school and planning the school's curriculum.

OHIO

Memorial to Classmate.—The seniors of the University of Cincinnati College of Medicine honored the memory of one of their classmates, Herbert N. Schiff, who was killed in an automobile accident during his sophomore year, by electing his father, Dr. Leon Schiff, an honorary member of the class. Dr. Schiff is associate professor of medicine in the college of medicine. About $10,000 has already been contributed to the Herbert N. Schiff memorial fund in the college of medicine.

Dr. Brower Receives Award.—Dr. Alonzo B. Brower, Dayton, was recently given the Alfred Stengel memorial award by the American College of Physicians. The award is made periodically to a fellow of the college "who, by virtue of his loyalty and service to the college, deserves an honor from it that is unique" and who has had "an outstanding influence in maintaining and advancing the best standard in medical education, medical practice and clinical research." In 1950, Dr. Brower established an endowment trust that provides an opportunity for worthy young physicians to go as visiting fellows to some institution for the purposes of observation and postgraduate study. Dr. Brower has been a member of the staff of St. Elizabeth Hospital and a director of the medical staff of Miami Valley Hospital for many years. He is a past president of the Montgomery County Medical Society.

PENNSYLVANIA

Dewees Public Health Scholarship.—The Pennsylvania Tuberculosis and Health Society announces the establishment of the Arthur Markley Dewees scholarship for advanced study of public health in recognition of the services of Dr. Dewees as executive secretary of the society from 1919 to 1952. The scholarship (stipend $2,000) is to be awarded annually to a Pennsylvanian for one year's graduate study in an accredited school of public health leading to a masters degree or in any recognized graduate school offering a curriculum designed to prepare a student for administrative or other professional service in tuberculosis or public health work.

Philadelphia

Personal.—A portrait of Dr. Charles M. Gruber, professor of pharmacology at Jefferson Medical College, Philadelphia, was recently presented to the college by the senior class.——Dr. Harold A. Taggart, assistant dean of Hahnemann Medical College and Hospital of Philadelphia, is serving as acting medical director of Hahnemann Hospital until a permanent appointment is made to fill the vacancy created when Dr. Charles E. Price left to become medical director of the General Hospital of Fresno County, Fresno, Calif.

Dr. Appel Heads Psychiatric Department.—Dr. Kenneth E. Appel, professor of psychiatry, University of Pennsylvania School of Medicine, was recently appointed as chairman of the department, succeeding Dr. Edward A. Strecker, who has been professor of psychiatry since 1931 and now becomes emeritus professor of psychiatry. Dr. Appel, who is also director of the Functional Diseases Service of the University of Pennsylvania Hospital, has been affiliated with the university since 1924. He was named president-elect of the American Psychiatric Association at the annual meeting in Los Angeles, and is president of the Marriage Council of Philadelphia, which recently became affiliated with the School of Medicine of the University of Pennsylvania. Dr. Strecker will continue as a member of the faculty of the graduate school of medicine and as chief of service and consultants at the Institute for Mental Hygiene, which is affiliated with the Pennsylvania Hospital.

SOUTH CAROLINA

Orthopedic School Group.—The following physicians of Charleston have volunteered to serve on the medical advisory committee for the new Easter Seal Orthopedic School: Joseph I. Waring, B. Owen Ravenel, Bachman S. Smith, John A. Siegling, and James J. Cleckley. They will screen all applications and make final decisions on enrollment in the school. Children attending the Easter Seal Orthopedic School will receive physical, occupational, and speech therapy, if necessary, in addition to special education.

TENNESSEE

Society News.—The Tennessee Diabetes Association has elected the following officers: president, Dr. Daniel R. Thomas, Knoxville, vice-president, Dr. Robert F. Ackerman, Memphis, and secretary-treasurer, Dr. Jean M. Hawkes, Memphis.——At its recent semiannual meeting the Middle Tennessee Medical Association elected Dr. Taylor Farrar, Shelbyville, president, Dr. S. Ogle Jones, Centerville, president-elect, and Dr. Frank G. Witherspoon, Nashville, secretary-treasurer. The next semiannual meeting of the association will be held in Murfreesboro on Nov. 19.——Officers of the newly formed Tennessee Heart Association include Dr. Benjamin F. Byrd Sr., Nashville, president, Dr. Philip H. Livingston, Chattanooga, vice-president, John W. Apperson, Memphis, secretary, and Laurie F. Pratt, Knoxville, treasurer. The state office of the association is in Nashville.

Personal.—Dr. Robert H. Hutcheson, Franklin, has been reappointed state health commissioner, a position that he had held since 1943 under three previous administrations. Dr. Hutcheson has served as a member of the A. M. A. House of Delegates and president of the State and Territorial Health Officers' Association, and has been assistant professor of medicine at Vanderbilt University School of Medicine, Nashville.——Dr. James A. Taylor, senior psychiatrist at VA Hospital (Kennedy), Memphis, has been appointed assistant professor of psychiatry and neurology and clinical director at the Gailor Memorial Psychiatric Hospital, Memphis. Dr. Taylor was previously affiliated with Kings Park State Hospital, Kings Park, N. Y.——Dr. Cyril J. Ruilmann, who has directed Gailor Memorial Psychiatric Hospital for the last 10 years, has been chosen by Governor Clement to head the new Tennessee Department of Mental Health.——During the week of April 12 Dr. R. Eustace Semmes, University of Tennessee College of Medicine, Memphis, occupied the George A. Ball Visiting Professorship in Surgery, recently inaugurated at the Indiana University School of Medicine, Indianapolis, by the James Whitcomb Riley Memorial Association.——Dr. Robert C. Little, associate professor of physiology at the University of Tennessee Medical Units, Memphis, has been appointed associate professor of medicine in the division of internal medicine. Dr. Little, author of numerous publications in cardiovascular research, will continue his investigations in this field, in addition to his teaching duties.——A portrait of Dr. F. Thomas Mitchell, chief, division of pediatrics, University of Tennessee College of Medicine, Memphis, was presented to the university June 11. The portrait is the gift of Memphis pediatricians. Dr. Mitchell has been on the staff of the College of Medicine since 1917.

TEXAS

Dr. Hertell Named for Red Cross Post.—Dr. Joseph Alan Hertell, who has served for 13 months as director and administrator of the Central Texas Red Cross regional blood center at Waco, has been appointed assistant director of the national Red Cross blood program.

Alumni Honor Dr. Moursund.—Honoring Dr. Walter H. Moursund Sr., retiring dean, the annual banquet of the Baylor University College of Medicine Alumni, recently held in Houston, was attended by more than 600 persons. Dr. Cecil F. Jorns, Houston, president of the Alumni Association, presided. An engraved watch was presented to Dr. Moursund. Officers elected were Dr. Richard H. Harrison Jr., Bryan, president-elect; Drs. Robert G. McCorkle Sr., San Antonio, and Hannibal L. Jaworski, Waco, vice-presidents; and Dr. John C. Haley, Houston, secretary-treasurer.

VERMONT

Biggs Award to Dr. Wadsworth.—Dr. Augustus B. Wadsworth, Manchester, director of the division of laboratories and research, New York State Department of Health, 1914-1945, is the recipient of the Hermann M. Biggs memorial award by the New York State Public Health Association. The citation described Dr. Wadsworth as "founder of the public health laboratory system of New York State, which today is outstanding in the world; developer of recognized standards for laboratory techniques in sanitation and in the diagnosis of infectious diseases; an outstanding investigator in the field of infection, and in the assay of therapeutic antisera; a pioneer in the study of endocarditis following pneumococcus infection; a leader in the development of the quantitative complement fixation test for the serodiagnosis of syphilis and other infectious diseases . . ."

VIRGINIA

Governor Appoints Tuberculosis Control Committee.—Gov. John S. Battle has appointed the following physicians on a committee "to serve in an advisory capacity to the State Board of Health and to make recommendations and suggestions as it deems appropriate" in the fight to eradicate tuberculosis: John T. T. Hundley, Lynchburg; Andrew D. Hart and Everett C. Drash, Charlottesville; Felix J. Brown and Edward S. Ray, Richmond; Frank R. Trigg and Samuel E. Hughes Jr., Norfolk; George W. Oast, Portsmouth; Lemuel R. Broome, Danville; and James N. Dudley, Roanoke.

Society News.—The Virginia Surgical Society, recently organized at a luncheon meeting at the Richmond Academy of Medicine Building, elected the following officers: president, Dr. Randolph H. Hoge, Richmond; vice-president, Dr. Hugh H. Trout Jr., Roanoke; secretary, Dr. Robert L. Payne Jr., Norfolk; and treasurer, Dr. William R. Hill, Richmond. Elected to the council were Drs. Edwin P. Lehman, Charlottesville; Isaac A. Bigger, Richmond; Edmund Horgan, Winchester; and Richard P. Bell Jr., Staunton. The next meeting of the society will be held during the annual meeting of the Medical Society of Virginia at Roanoke, Oct. 18-21.

WEST VIRGINIA

University News.—Daniel Thomas Watts, Ph.D., Charlottesville, associate professor of pharmacology at the University of Virginia School of Medicine since 1949, has accepted appointment as professor and head of the department of pharmacology at West Virginia University School of Medicine, Morgantown. Dr. Watts, who served in the U. S. Naval Reserve as an ensign until 1947 and was released with the rank of lieutenant commander, taught and conducted research in aviation physiology.

Meeting on Infectious Diseases.—A program on infectious diseases, sponsored by Lederle Laboratories, will be presented by the West Virginia Academy of General Practice at the Hotel Fairmont in Fairmont, Aug. 16. Subjects to be discussed include rabies, poliomyelitis, infectious hepatitis, genitourinary infections, atypical pneumonia, infectious pneumonia, infectious mononucleosis, and histoplasmosis. The morning session, which will begin at 10 o'clock, will be followed by a luncheon at the Hotel Fairmont, with Lederle Laboratories as host. Panel discussions will follow both the morning and the afternoon programs. All members of the medical profession in West Virginia are invited to attend the meeting.

WYOMING

State Medical Election.—At the annual meeting the Wyoming State Medical Society installed Dr. James W. Sampson, Sheridan, as president and elected Dr. Bernard J. Sullivan, Laramie, president-elect, Dr. Nels A. Vicklund, Thermopolis, vice-president, Dr. Royce D. Tebbet, Casper, secretary, and Dr. Curtis L. Rogers, Sheridan, treasurer. The annual session of 1954 will be held during the first week in June in Sheridan.

GENERAL

Visiting Scientists.—Dr. H. E. Holling of the Medical Research Council's Clinical Research Unit at Guy's Hospital, London, England, is spending some time in the United States at the invitation of the University of Pennsylvania School of Medicine, Philadelphia. He will also make a few visits on behalf of the Medical Research Council, including attendance at the International Physiology Congress in Montreal. Address: U. K. Scientific Mission, 1800 K St., N.W., Washington, D. C.——Dr. A. D. Macrae, Public Health Laboratory Service (directed by the Medical Research Council on behalf of the Ministry of Health, United Kingdom), is completing a year at Yale University under a Smith-Mundt award supplemented by assistance from the Yale authorities.

Diathermy Machines for Korea.—Pointing out that a Federal Communications Commission ruling has outlawed use in the United States of thousands of short-wave diathermy machines whose frequencies interfere with radio and television programs as well as with police and defense communication channels, Dr. Howard A. Rusk, director of the Institute for Physical Medicine and Rehabilitation, New York University-Bellevue Medical Center, advises that these machines are needed for treatment of crippled and sick persons in Korea. Most of the machines built before 1947 will have to be scrapped. Dr. Rusk, who is medical adviser to the American-Korean Foundation (303 Lexington Ave., New York 16), which is currently conducting a campaign for 5 million dollars to provide emergency relief for Korea, states that the foundation has received requests for more than 25 machines. Three, a gift from the physicians' supply firm of Cole, Dominick and Rogg, Inc., will be used at a 900 bed rehabilitation center that the foundation is helping to set up and staff at Tongnae in Korea. Requests for diathermy equipment have also been received from the Severance Hospital and Maryknoll Sisters Clinic in Pusan.

Congress on Electroencephalography.—The International Congress of Electroencephalography and Clinical Neurophysiology will be held at Agassiz House, Radcliffe College, Cambridge, Mass., Aug. 16-21. The presidential address will be delivered at 1:30 p. m. by Dr. Alexander Forbes, Boston. Symposiums to be presented in the Agassiz House auditorium include: "Recent Developments in Electroencephalographic Techniques," "Physiological Basis of the Electroencephalogram," "Interpretation of the Electroencephalogram," "Evaluation of Activation of the Electroencephalogram," "Interrelationships Between Cortex and Subcortical Structures," and "Characteristics and Significance of Seizure Discharges," in collaboration with the American League Against Epilepsy. Tuesday evening will be devoted to cinematographic presentations. After the morning session on Wednesday the day has been reserved for a social afternoon and evening, which will include a shore party at Crane Beach and Bird Sanctuary at Ipswich. The informal dinner at the Hotel Continental Friday, 8 p. m., will be preceded by a cocktail party in the gardens of the hotel for foreign members and their wives, who will be guests of the American League Against Epilepsy.

Gerontologists Meet in San Francisco.—The annual scientific meeting of the Gerontological Society, Inc., will be held at the Hotel Mark Hopkins, San Francisco, Aug. 25-27. The general session will open Tuesday, 9:30 a. m., in the Room of the Dons with presentation of "New Roles for the Aging," "Gerontological Implications in Pharmacology," "Mental Health and Aging," "Biochemical Aspects of Aging," and "Education for Aging." The sessions will end with a symposium on arteriosclerosis Thursday, 3:15 p. m., in the Golden Empire Room, when Albert I. Lansing, Ph.D., St. Louis, will serve as chairman for the following panel: Dr. James F. Rinehart, San Francisco, Dr. Charles A. Woerner, Louisville, Dr. Silas M. Evans, Milwaukee, and Henry S. Simms, Ph.D., New York. The San Francisco Regional Office of the U. S. Department of Health, Education and Welfare has arranged a program on motion pictures on aging for Tuesday evening in the Room of the Dons, with Dr. Henry C. Schumacher, San Francisco, regional mental health consultant, Public Health Service, as discussant. Cocktails, Thursday, 6 p. m., will precede the annual dinner in Peacock Court, which will be addressed by Dr. Emund V. Cowdry, St. Louis, president, and Dr. J. H. Sheldon, Royal Hospital, Wolverhampton, England. The National Committee on Aging of the National Social Welfare Assembly will hold an all day meeting, Aug. 28, at Hotel Mark Hopkins. The luncheon meeting, "In the Vanguard of Service Programs for Older People on the West Coast," and the afternoon sessions will be open meetings. The morning will be devoted to a meeting of the West Coast Advisory Committee to the project on criteria for the continued employment of older workers and a business session on activities and plans of the National Committee on the Aging. Attendance at these meetings will be limited to members of the committee and their invited guests.

Prevalence of Poliomyelitis.—According to the National Office of Vital Statistics, the following number of reported cases of poliomyelitis occurred in the United States, its territories, and possessions in the weeks ended as indicated:

Area	July 18, 1953		July 19, 1952 Total

Communicable Diseases During the First Half of 1953.—According to a report from the Department of Health, Education and Welfare, U. S. Public Health Service, comparison of communicable disease cases reported during the first half of 1953 and those reported during the like period in 1952 shows the following results:

Disease	First 26 Weeks 1953	First 26 Weeks 1952
Anthrax	20	19
Botulism	6	8
Brucellosis (undulant fever)	826	1,061
Diphtheria	1,050	1,403
Encephalitis, acute infectious	530	620
Hepatitis, infectious and serum	17,390	9,001
Malaria: civilian	231	423
military	289	2,516
Measles	388,581	622,900

Tularemia	280	345
Typhoid	888	944
Typhus, endemic	105	86
Whooping cough	16,991	27,329
Rabies in animals	4,033	4,636

Annual Meeting of National Medical Association.—The annual meeting of the National Medical Association will be held at the Meharry Medical Center, Nashville, Tenn., Aug. 10-14, under the presidency of Dr. Whittier C. Atkinson, Coatesville, Pa. Monday morning the public health section will hold an open public meeting in the auditorium. The general sessions will open Tuesday, 9 a. m., when a panel honoring the Nashville founders of the association will be presented. The presidential address will be delivered shortly before adjournment. The medical section will hold clinicopathological conferences Tuesday, 4:30 p. m., Thursday and Friday, 11:30 a. m., and a panel discussion on blood diseases Wednesday at 4 p. m. The section on pediatrics will present a clinical panel on "Common Problems Arising in the Care of Infants and Children" Tuesday, 4 p. m. During pediatric ward rounds at the George W. Hubbard Hospital of Meharry Medical College Wednesday afternoon there will be a "Cine Lecture on Ventricular Filbrillation and Defibrillation" 2:10 p. m., and at 4:30 p. m. a fracture consultation panel. The section on surgery, urology, and orthopedics, which will share in this program, will conduct operative clinics at Vanderbilt University on Tuesday morning and at Hubbard Hospital on Thursday and Friday mornings, and will hold an open meeting in the auditorium at Meharry on Wednesday. A panel discussion on peptic ulcers will be presented at 9:40 a. m., and at 11:15 a. m. Dr. Clarence S. Greene, associate professor of surgery, Howard University College of Medicine, Washington, D. C., will deliver the Stubbs Oration in Surgery on "Astrocytomas." On Thursday, 10:30 a. m., during the open meeting in the amphitheater the radiology section will present a symposium on "Problems of the Urinary Tract with Special Reference to Radiologic Procedures." The final session of the medical section on Friday will feature a symposium on cancer at 10:30 a. m. by Drs. Jack E. White, assistant professor of surgery and director of the Cancer Detection Clinic of Freedmen's Hospital, Washington, D. C., John F. W. King, Wilmington, Del., director of surgery section, American Cancer Society, and Ralph R. Braund, coordinator of cancer, University of Tennessee College of Medicine, Memphis. Tuesday night has been reserved for the welcome night program in the Mount Olive Baptist Church, 9th and Charlotte, at which Dr. Daniel T. Rolfe, Nashville, will preside. The president's grand ball will be held Thursday at 9 p. m., and the incoming president, Dr. A. Porter Davis, Kansas City, Kan., will deliver an address immediately preceding adjournment of the general sessions Friday afternoon.

MEETINGS

AMERICAN MEDICAL ASSOCIATION: Dr. George F. Lull, 535 North Dearborn St., Chicago 10, Secretary.

1953 Clinical Session, St. Louis, Dec. 1-4.
1954 Annual Session, San Francisco, June 21-25.
1954 Clinical Session, Miami, Florida, Nov. 30-Dec. 3.
1955 Annual Session, Atlantic City, N. J., June 6-10.
1955 Clinical Session, Boston, Nov. 29-Dec. 2.

Public Relations Institute, Drake Hotel, Chicago, Sept. 2-3. Mr. Leo E. Brown, 535 North Dearborn St., Chicago 10, Director.

American Association of Obstetricians, Gynecologists and Abdominal Surgeons, The Homestead, Hot Springs, Va., Sept. 10-12. Dr. William F. Mengert, 2211 Oak Lawn Ave., Dallas, Texas, Secretary.

American Congress of Physical Medicine, Palmer House, Chicago, Aug. 31-Sept. 4. Dr. Walter J. Zeiter, 30 North Michigan Ave., Chicago 2, Executive Director.

American Dietetic Association, Los Angeles, Aug. 24-28. Miss Ruth M. Yakel, 620 N. Michigan Ave., Chicago 11, Executive Secretary.

American Electroencephalographic Society, Commander and Continental Hotels, Cambridge, Mass., Aug. 17-22. Dr. John A. Abbott, Massachusetts General Hospital, Boston 14, Secretary.

American Hospital Association, San Francisco, Aug. 31-Sept. 3. Mr. George Bugbee, 18 East Division St., Chicago 11, Executive Director.

American Society for Pharmacology and Experimental Therapeutics, Fall Meeting, Yale University, New Haven, Conn., Sept. 7-9. Dr. Carl C. Pfeiffer, 1853 West Polk St., Chicago 12, Secretary.

Biological Photographic Association, Hotel Statler, Los Angeles, Aug. 31-Sept. 3. Miss Jane H. Waters, 533 West 57th St., New York 19, Secretary.

Gerontological Society, Mark Hopkins Hotel, San Francisco, Aug. 25-27. Dr. Nathan W. Shock, Baltimore City Hospitals, Baltimore 24, Secretary.

Montana Medical Association, Northern Hotel, Billings, Sept. 17-20. Mr. L. R. Hegland, 104 North Broadway, Billings, Executive Secretary.

National Medical Association, Nashville, Tenn., Aug. 10-14. Dr. John T. Givens, 1108 Church St., Norfolk 10, Va., Executive Secretary.

North Pacific Society of Internal Medicine, Harrison, B. C., Sept. 18-19. Dr. Clarence C. Pearson, 1115 Terry Ave., Seattle 1, Wash., Secretary.

Regional Meetings, American College of Physicians:

- North Dakota, Fargo, Sept. 12. Dr. Robert B. Radl, 221 Fifth St., Bismarck, Governor.
- Arkansas-Oklahoma, Tulsa, Okla., Sept. 19. Dr. Wann Langston, 117 North Broadway, Oklahoma City 2, Governor.

Society of American Bacteriologists, Palace Hotel, San Francisco, Aug. 10-14. Dr. John H. Bailey, Sterling-Winthrop Research Institute, Rensselaer, N. Y., Secretary.

U. S. Chapter, International College of Surgeons, Waldorf-Astoria, New York, Sept. 13-17. Dr. Karl Meyer, 1516 Lake Shore Drive, Chicago 10, Secretary.

Utah State Medical Association, Salt Lake City, Sept. 10-12. Dr. Homer E. Smith, 42 South Fifth East St., Salt Lake City 2, Secretary.

Washington State Medical Association, Olympic Hotel, Seattle, Sept. 13-16. Dr. Bruce Zimmerman, 338 White-Henry-Stuart Bldg., Seattle 1, Secretary.

FOREIGN

Association of Surgeons of Great Britain and Ireland, Leeds, England, May 13-15, 1954. Dr. Henry W. S. Wright, 45 Lincoln's Inn Fields, London W.C.2, England, Honorary Secretary.

Canadian Medical Association, Vancouver, B. C., Canada, June 18-22, 1954. Dr. T. C. Routley, 135 St. Clair Ave. W., Toronto 5, Ont., Canada, General Secretary.

Congress of International Anesthesia Research Society, Chateau Frontenac, Quebec, Canada, October 26-29. Dr. A. William Friend, 515 Nome Ave., Akron 20, Ohio, Chairman, Program Committee.

Congress of the International Association of Limnology, Cambridge and Windermere, England, Aug. 20-30. For information write: Professor G. C. Hutchinson, Osborn Zoological Laboratory, Yale University, New Haven, Conn., U. S. A.

Congress of the International League Against Rheumatism, Geneva, Switzerland and Aix-les-Bains, France, Aug. 23-29. For information write: Dr. W. Tegner, The London Hospital, London E.1, England.

Congress of the International Society of Angiology, Lisbon, Portugal, Sept. 18-20. Dr. Henry Haimovici, 105 East 90th St., New York 28, N. Y., U. S. A., Secretary.

Congress of the International Society of Surgery, Lisbon, Portugal, Sept. 14-20. Dr. L. Dejardin, 141, rue Belliard, Brussels, Belgium, General Secretary.

Interim Meeting, Aero Medical Association, University of Brussels Medical School, Brussels, Belgium, Sept. 24-27. Dr. Andre Allard, Medical Director of SABENA, 145 Rue Royale, Brussels, Belgium, Secretary.

Roche, Arthur Felix ⊕ Hartford, Conn.; Georgetown University School of Medicine, Washington, D. C., 1917; member of the American Academy of Allergy; served during World War I; affiliated with St. Francis and McCook hospitals; died April 11, aged 59, of coronary thrombosis.

Rodgers, Lewis Aretus ⊕ Oskaloosa, Iowa; State University of Iowa College of Medicine, Iowa City, 1889; past president of the Mahaska County Medical Society; died April 20, aged 89, of cerebral hemorrhage.

Salinger, Simon F., Chicago; Western Pennsylvania Medical College, Pittsburgh, 1897; died June 4, aged 92, of coronary heart disease and arteriosclerosis.

Sawyer, Alpha Reuben ⊕ Lexington, Mass.; McGill University Faculty of Medicine, Montreal, Canada, 1905; member of the American Urological Association; died May 13, aged 71.

Schaefer, John F. ⊕ New York City; Schlesische Friedrich-Wilhelms-Universität Medizinische Fakultät, Breslau, Germany, 1927; formerly affiliated with the Indian Service; died in Brentwood, N. Y., April 15, aged 51.

Schamberg, Morris I., New York City; Medico-Chirurgical College of Philadelphia, 1898; also a graduate in dentistry; formerly professor of oral surgery at the New York Post-Graduate Medical School, and his alma mater; veteran of the Spanish-American War; served on the staff of the Bronx Hospital; died May 20, aged 78.

Selo, Herbert Louis ⊕ Findlay, Ohio; Universität Köln (Cologne) Medizinische Fakultät, Köln, Prussia, Germany, 1923; member of the American Academy of General Practice; on the staff of the Blanchard Valley Hospital; died April 9, aged 54, of coronary thrombosis.

Simmons, John A. ⊕ Arcadia, Fla.; University of Arkansas School of Medicine, Little Rock, 1905; died April 25, aged 75, of coronary thrombosis and coronary sclerosis.

Smith, Glenn Jones, Amite, La.; American Medical College, St. Louis, 1906; member of the American Psychiatric Association; served during World War I; for many years served on the state board of education; for many years superintendent of the East Louisiana State Hospital at Jackson; died May 24, aged 71, of cerebral hemorrhage.

Smith, Victor Conway ⊕ New Orleans; Medical Department of Tulane University of Louisiana, New Orleans, 1899; member of the American Academy of Ophthalmology and Otolaryngology; fellow of the American College of Surgeons; formerly on the faculty of his alma mater; member of the staff of the Eye, Ear, Nose and Throat Hospital, Illinois Central Railroad Hospital, and the Baptist Hospital, where he died May 19, aged 78, of acute leukemia.

Smith, Warren Clifton, Benton, Miss.; Memphis (Tenn.) Hospital Medical College, 1906; served on the staffs of the Kings Daughters Hospital and Yazoo Clinic and Hospital in Yazoo City; died May 1, aged 68, of arteriosclerosis.

Smith, Will Remeses, Huntington Park, Calif.; Marion-Sims College of Medicine, St. Louis, 1895; died in VA Center, Los Angeles, March 25, aged 85, of terminal bronchopneumonia and adenocarcinoma of the prostate.

Staton, Torrence Ripley ⊕ Atlanta, Ga.; Emory University School of Medicine, Atlanta, 1930; served during World War II; died near Forsythe July 5, aged 46, of injuries received in a private plane accident.

Stimson, George William ⊕ Warren, Ohio; University of Pennsylvania School of Medicine, Philadelphia, 1903; specialist certified by the American Board of Otolaryngology; member of the American Academy of Ophthalmology and Otolaryngology; fellow of the American College of Surgeons; on the staffs of the Warren City Hospital and Trumbull Memorial Hospital; died April 20, aged 73.

Stocker, Harry ⊕ Detroit; Northwestern University Medical School, Chicago, 1923; on the staffs of the Sinai and East Side General hospitals; died May 5, aged 56, of coronary disease.

Sum, Othmar John, Barnhart, Mo.; St. Louis University School of Medicine, 1921; served during World War I; died May 1, aged 61, of heart disease.

Swift, Samuel ⊕ Bronxville, N. Y.; Columbia University College of Physicians and Surgeons, New York, 1913; fellow of the American College of Surgeons; died in the Lawrence Hospital May 30, aged 66, of acute pulmonary edema and hypertension.

Tenczar, John Francis ⊕ Chicago; University of Illinois College of Medicine, Chicago, 1927; on the staff of St. Mary of Nazareth Hospital, where he died May 22, aged 53, of carcinomatosis.

Thieme, Harry Lankford ⊕ St. Louis; St. Louis University School of Medicine, 1924; member of the Industrial Medical Association; affiliated with Barnes, Jewish, Missouri Baptist, and Alexian Brothers hospitals; died May 29, aged 51, of injuries received in an automobile accident.

Thornton, Francis Eugene ⊕ Chicago; Bennett Medical College, Chicago, 1888; an Associate Fellow of the American Medical Association; formerly on the faculty of his alma mater; affiliated with the Norwegian American Hospital and for many years on the staff of the Cook County Hospital; died May 14, aged 88, of carcinoma of the bladder.

Townsend, Wilmot Charles ⊕ Hartford, Conn.; Harvard Medical School, Boston, 1925; certified by the National Board of Medical Examiners; fellow of the American College of Physicians; served during World War I; received the Bronze Star for his services in the Mediterranean theatre during World War II; consultant, New Britain (Conn.) General Hospital and the Institute for Living; on the staff of the Hartford Hospital, where he died May 10, aged 55, of coronary disease.

Van Studdiford, Martin Thomas ⊕ New Orleans; Tulane University of Louisiana School of Medicine, New Orleans, 1918; professor of clinical dermatology at his alma mater; specialist certified by the American Board of Dermatology and Syphilology; member of the American Dermatological Association and the American Academy of Dermatology and Syphilology; affiliated with National Leprosarium in Carville, La., U. S. Marine Hospital, Hotel Dieu, Sisters' Hospital, and Charity Hospital; died May 15, aged 62, of leukemia.

Veneruso, Leonard Charles ⊕ Trumbull, Conn.; New York Medical College, Flower and Fifth Avenue Hospitals, New York, 1942; certified by the National Board of Medical Examiners; served during World War II; affiliated with Bridgeport (Conn.) Hospital, where he died May 1, aged 35, of acute coronary occlusion.

Wadsworth, John V. ⊕ Buffalo; University of Buffalo School of Medicine, 1921; affiliated with Edward J. Meyer Memorial Hospital; on the staffs of the Buffalo General Hospital and the Millard Fillmore Hospital, where he died May 6, aged 58, of acute myocardial infarction.

Wahl, Spencer Alwyn ⊕ Cleveland; Western Reserve University School of Medicine, Cleveland, 1920; died in Bethesda, Md., May 21, aged 57, of cerebral hemorrhage and hypertension.

Wallin, Maurice Benjamin, Chicago; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1907; died in Rochester, Minn., May 22, aged 65, of carcinoma of the lung.

Walton, Josiah Harry ⊕ Clayton, Mo.; Barnes Medical College, St. Louis, 1902; died May 30, aged 79, of carcinoma.

Wenstrand, David E. W. ⊕ Tryon, N. C.; Northwestern University Medical School, Chicago, 1900; member of the State Medical Society of Wisconsin; past president, vice-president, and secretary of the Milwaukee Academy of Medicine; an Associate Fellow of the American Medical Association; past president and vice-president of the Association of Life Insurance Medical Directors; formerly director of the Northwestern Mutual Life Insurance Company; died June 4, aged 77, of coronary occlusion.

White, Wendell Jones ⊕ Vinita, Okla.; University of Arkansas School of Medicine, Little Rock, 1948; member of the Arkansas Medical Society; served during World War II; affiliated with Eastern State Hospital; died May 10, aged 30.

Widing, Herbert Andrew ⊕ Philadelphia; Jefferson Medical College of Philadelphia, 1927; affiliated with Jefferson and Presbyterian hospitals; died May 30, aged 52.

Wilder, Don Eugene ⊕ Booneville, Ky.; University of Louisville School of Medicine, 1929; served as health officer of Carter, Owsley, Lawrence, and Breathitt counties; formerly secretary and treasurer of the Carter County Medical Society; died in St. Joseph Hospital, Lexington, April 5, aged 48, of a fractured skull sustained in a fall.

Williams, John Watkins, Williamston, N. C.; University of Maryland School of Medicine, Baltimore, 1906; health officer of Martin County; formerly health officer of Asheville; served as director of Quachita Parish (La.) Health Unit; past president of the North Carolina Public Health Association; died in Martin General Hospital May 19, aged 68, of uremia and auricular fibrillation.

Worthington, Ernest Jerome ⊕ Chicago; Chicago College of Medicine and Surgery, 1917; past president of the West Side Branch of the Chicago Medical Society; past president of the West Side Hospital; served on the staff of Bethany Hospital; died May 23, aged 62.

Wright, Harper ⊕ Oklahoma City, Okla.; Atlanta College of Physicians and Surgeons, 1913; past president of the Oklahoma State Board of Medical Examiners; on the staff of the Wesley Hospital; died in Cuthbert, Ga., May 30, aged 65, of coronary thrombosis.

DIED WHILE IN MILITARY SERVICE

Goodwin, Robert Franklin, Bremerton, Wash.; University of Tennessee College of Medicine, Memphis, 1949; interned at the Wichita (Kan.) Hospital; lieutenant (jg), U. S. Naval Reserve; served at the Naval Hospital in Bremerton at the time of his death April 1, aged 34, of injuries received in an automobile accident.

Richards, Arthur Charles Jr. ⊕ Ambler, Pa.; born in Philadelphia Aug. 2, 1914; Jefferson Medical College of Philadelphia, 1943; interned at the Williamsport (Pa.) Hospital; served a residency in obstetrics and gynecology at the Grace-New Haven Community Hospital in New Haven, Conn., and the Pennsylvania Hospital in Philadelphia; captain, medical corps, U. S. Army Reserve, serving in Korea since January as a medical adviser to the 6th ROK Division; died May 14, aged 38, of injuries received in a helicopter crash near Hwanchon Reservoir, Korea.

GOVERNMENT SERVICES

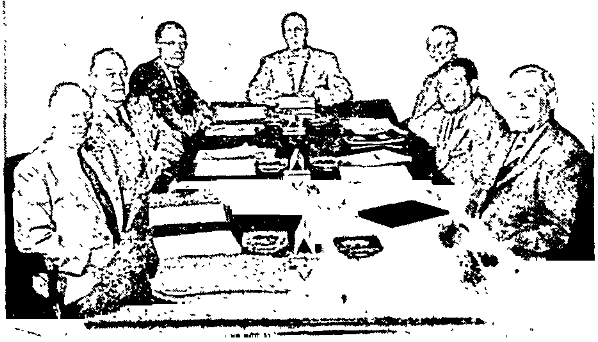
ARMY

Personal.—Lieut. Col. Charles D. Shields (MC) formerly commissioner of health for Buffalo, N. Y., has reported to the Army Surgeon General's office for duty as chief physical medicine consultant in the Professional Division, effective July 1. Colonel Shields replaces Col. Emmett M. Smith (MC), who has been assigned to Europe.

Colonel Shields' most recent assignment was as chief of the Physical Medicine Service at Brooke Army Hospital, Fort Sam Houston, Texas. During World War II, he served as commanding officer of the 87th Station and 141st General hospitals and later as public health officer with the Allied Control Commission in Italy. From 1944 to 1946 he served as health officer for Bavaria. Colonel Shields left the Army in 1946 to accept a position with the city of Buffalo as commissioner of health. He joined the Regular Army in 1947.

DEPARTMENT OF DEFENSE

Medical Advisory Council.—The Armed Forces Medical Policy Council was dissolved on April 1, 1953. At the same time, the Secretary of Defense appointed a Civilian Health and Medical Advisory Council, consisting of six members of the health and medical professions of the United States.



Medical advisory council (left to right): Dr. William S. Middleton; Dr. Anthony J. J. Rourke; Dr. Dwight L. Wilbur; Dr. Melvin A. Casberg, assistant to the Secretary of Defense (Health and Medical); Dr. Alfred R. Shands Jr.; Dr. Isidor S. Ravdin; and James P. Hollers, D.D.S.

NAVY

Personal.—Capt. Ashton Graybiel (MC) has been chosen president-elect of the American College of Cardiology. Captain Graybiel, now Coordinator of Medical Research, Naval School of Aviation Medicine, Pensacola, Fla., was awarded the Legion of Merit in 1952 for outstanding service as director of research at the School of Aviation Medicine. The Aero-Medical Association awarded its Lyster award for 1950 to Captain Graybiel for outstanding scientific contributions to aviation medicine. The citation accompanying the award recognized his co-authorship of the book "Electrocardiography in Practice."

AIR FORCE

Personal.—Dr. John A. Schilling, assistant professor of surgery at the University of Rochester School of Medicine, Rochester, N. Y., has been appointed head of the department of surgery at the U. S. Air Force School of Aviation Medicine, Randolph Field, Texas.

PUBLIC HEALTH SERVICE

Radioactive Cortisone Available.—A limited supply of radioactive cortisone and hydrocortisone is now available without charge to qualified investigators through funds supplied by the Public Health Service's National Institute of Arthritis and Metabolic Diseases. Both are labeled at position 4 with C^{14}; cortisone has a specific activity of 0.49 mc./m. mole; and hydrocortisone a specific activity of 1.47 mc./m. mole. Requests, in the form of a letter concisely describing the proposed research, should be sent to the Division of Research Grants, National Institutes of Health, Bethesda 14, Md. Transfer and use of these materials are subject to current Atomic Energy Commission regulations.

Personal.—Dr. Clifton K. Himmelsbach has been appointed assistant chief, division of hospitals, U. S. Public Health Service, effective July 20. Dr. Himmelsbach was formerly medical officer in charge of the P. H. S. Outpatient Clinic, Washington, D. C. He succeeds Dr. Myron D. Miller, who has been appointed medical officer in charge of the P. H. S. Hospital, Seattle.——Dr. James R. Shaw has been appointed chief medical officer of the Bureau of Indian Affairs, U. S. Department of the Interior, effective July 13. Dr. Shaw was formerly chief of the division of hospitals, U. S. Public Health Service. He succeeds Dr. Fred Foard, who has retired from the Public Health Service.

VETERANS ADMINISTRATION

Personal.—Dr. Benedict Nagler, associate professor of neuropsychiatry at the Medical College of Virginia and chief of the neuropsychiatric service at the VA Hospital in Richmond, Va., will become chief of the neurology section of the psychiatry and neurology division, department of medicine and surgery, effective July 19, 1953. Dr. Nagler will succeed Dr. Tiffany Lawyer Jr., who is leaving the Veterans Administration to accept a teaching assignment in Georgetown University Medical School, Washington, D. C. In his new position, Dr. Nagler will coordinate policies in the treatment of more than 10,000 veteran patients suffering from neurological diseases in VA Hospitals and Outpatient Clinics. He will serve under Dr. Harvey J. Tompkins, chief of the psychiatry and neurology division.——Dr. Peter A. Peffer, manager of the VA Hospital at Perry Point, Md., is to be manager of the new 958 bed neuropsychiatric VA Hospital nearing completion at Brockton, Mass. Dr. Earl P. Brannon, chief of professional services at the Perry Point hospital, has been appointed manager at that installation. Dr. Joseph L. Campbell, former manager of the VA Hospital at Butler, Pa., becomes manager of the VA Hospital in Dwight, Ill. He succeeds Dr. M. H. Fineberg, recently transferred as manager of the VA Hospital in Wilkes-Barre, Pa. Dr. Fineberg was certified by the American Board of Internal Medicine in 1939, after 12 years of private practice in Cleveland. He served in the Army Medical Corps from July, 1941, until June, 1946.——Eugene K. Ricker, manager of the VA Hospital in Fort Bayard, N. Mex., becomes manager of the VA Domiciliary at Camp White, Ore. He succeeds Paul A. Hatton, transferred to the VA Center in Hot Springs, S. D.——Dr. Louis B. Newman, chief, Physical Medicine and Rehabilitation Service, VA Hospital, Hines, Ill., addressed the staff of the Memorial Hospital, St. Joseph, Mich., May 26, on "The Value of Physical Medicine and Rehabilitation."——Dr. John G. Hood of Richmond, Va., has been appointed manager of the VA Hospital in the Bronx, New York City, to succeed Dr. Ralph G. Devoe, who is retiring.

FOREIGN LETTERS

BRAZIL

Hematological Aspects of Lupus Erythematosus Disseminatus.—Disseminated lupus erythematosus causes a true and extensive reticuloendotheliosis, involving the reticulohistiocytes and the fundamental substance of the collagen as well. It produces a real "mesenchymatosis," explaining the serious alterations of the hematopoietic organs and the various deviations in the blood picture. Dr. Michel Jamba, of the department of clinical medicine, São Paulo State University, in collaboration with the staff of the central laboratory of the Hospital das Clinicas, published a report of repeated examinations in 15 cases of disseminated lupus erythematosus (*Revista Paulista de Medicina* 42:171, 1953). The hematological aspects of the reticuloendotheliosis were analyzed to emphasize some points that may help the practitioner in making an early diagnosis of the disease. The authors stress the importance of noncutaneous forms, pointing out that most of them (11 out of 15, or 73.3%) have a chronic course that permits the distinction of four principal forms, according to the presence or absence of cutaneous lesions. The acute visceral form of the disease may occur in some cases without skin lesions, this being the reason why the disease is called "disseminated lupus" or "lupous collagenosis."

In this series, only 2 of 15 patients were males and 2 were of older age (58 and 61 years). Anemia occurred in all patients at some time during the natural course of the disease. Leukopenia was found in only two patients, and leukocytosis was not uncommon in connection with intercurrent complications or as a result of the treatment. Platelet reduction occurred in four patients but without simultaneous leukopenia. A male patient had thrombocytopenic purpura, with petechiae, purpuric maculas, and intestinal hemorrhage. In patients with slight hypertension, renal lesions, and hepatic and splenic enlargement, the positivity of the lupus erythematosus cell (Hargraves) test led to the exact clinical diagnosis. The bone marrow study in seven patients permitted the demonstration of some inhibition of the neutrophilic granulocyte maturation, and a relative hypoplasia of the erythroblastic cells, and in all patients an increase of the plasmocytes.

The lupus erythematosus cell test is, in the authors' opinion, pathognomonic. When performed in 97 cases, it was not positive in 28 other pathological conditions. In order that the test may be performed without error, it is necessary to use some "reactive" leukocytes, as some white blood cells are "hyporeactive" or even "nonreactive" to the gamma globulin responsible for the lupus erythematosus cell phenomenon. As the clinical picture of disseminated lupus erythematosus is very complex and frequently ill-defined, the authors believe that the lupus erythematosus cell test is indispensable when, without clear explanation, there are symptoms and signs like elevation of temperature, accelerated blood sedimentation rate, anemia, hyperglobulinemia, and plasmocytic infiltration of the bone marrow, idiopathic thrombocytopenia with sudden onset late in life, liver and spleen enlargement without hemopathic disorders associated with elevation of temperature, pulmonary infiltrations associated with temperature elevations, and recurrent pleural effusions. In the performance of the test, they recommend the use of positive plasma as a control of the reactivity of the "leukocytic cream" that is to be mixed with the plasma being tested.

Humoral Immunity of Dogs Infected with Trypanosoma Cruzi.—In the last two years, Drs. Julio Muniz and Rostan Soares, at the Institute of Malariology, National Department of Health, have been studying the various aspects of immunity in dogs experimentally infected with Trypanosoma (Schizotrypanum) cruzi. They have prepared a report for the *Revista Brasileira de Malariologia*, with the principal results of their work up to the present time. They performed, with the techniques already described in previous papers, the following tests: complement fixation test, precipitin test, agglutination reaction, and hemolytic and agglutination powers for sheep's blood cells.

The conclusion of the authors is that the establishment of immunity of dogs against T. cruzi follows a general course similar to that in man, though some differences may be recognized. Thus, the agglutinin content was found to be lower than in man, specially in the patent stage of the disease. Contrarily, the precipitin content showed itself to be markedly higher and more persistent, particularly in the postpatent stage. A close relationship between the agglutination and the precipitation powers, such as occurs in man, was not observed in the authors' experiments. Another difference disclosed by the experiments was the absence of antibodies of the heterophilic type, which are found in high concentration in human infections, especially during the patent stage. A justifiable explanation of this fact, in the opinion of the authors, is the presence of Forssman's antigen in the dog.

Pulmonary Resections.—Dr. Jesse Teixeira, head surgeon of the Rio de Janeiro Santa Maria Tuberculosis Hospital, published in *Revista Brasileira de Cirurgia* (25:551, 1952) a comprehensive report on 38 consecutive cases of pulmonary resections with some valuable information for the practitioner. After a review of the fundamental phases of the historic development of the methods for this kind of operation and a description of techniques, the author analyzes the indication for pulmonary resection, especially in connection with lung tumors, chronic bronchopulmonary suppurations, and pulmonary tuberculosis. He illustrates each of these points with the experience of his cases, a summary of which may be presented as follows. In 7 cases the operation was done for pulmonary tumors, in 17 for bronchopulmonary suppurations, and in 14 for pulmonary tuberculosis. Total pneumonectomies were done in 24 cases (on the right in 10 and the left in 14). Lobectomies were done in 14 cases, with one lobe being removed in 13 cases and 2 lobes in 1. Anesthesia with spontaneous breathing was used in the first series of 15 and anesthesia with controlled breathing in the second series of 24. There were nine deaths immediately postoperatively in the first series and none in the second. The causes of death in the first series were irreversible shock in three cases, cerebral and coronary gaseous embolism in 1 (established at autopsy), cardiac arrest during the operation in two cases, and uncontrollable hemorrhage during the operation in one case. Two patients died suddenly with change of posture at the end of the procedure. There were two deaths that did not occur immediately after the operation in the first series (one due to tuberculosis after 7 days and one due to cancer after 18 months), and three in the second series (one from tuberculosis after 12 days, one from cancer after 3 months, and one from tuberculosis after 7 months). The author stresses the importance of modern techniques, which decrease the immediate postoperative mortality, and emphasizes the superiority of anesthesia with controlled respiratory methods in thoracic surgery.

Intestinal Schistosomiasis in São Paulo.—Drs. J. Alves Meira and José M. Ferreira, professor and assistant professor of tropical medicine, São Paulo State University, reported three more cases of intestinal schistosomiasis in the interior of the state of São Paulo. In one case in which the patient lived at Ourinhos the disease was considered truly autochtonous, since infected snails were found by Dr. Luis Rey in a small stream of the vicinity. The Ourinhos focus was the first to be discovered in the uplands of São Paulo. The other two cases were discovered at Palmital and Ipauçú, where, in previous surveys, Dr. Samuel Pessoa and Dr. J. O. Coutinho have found uninfected planorbid snails of the genus Astralorbis. Considering the present great

---

The items in these letters are contributed by regular correspondents in the various foreign countries.

migration of persons from highly infected tropical districts of Brazil, and the possibility of the presence of snails of susceptible species in the São Paulo uplands, the authors foresee the existence of new foci of the disease in the interior of São Paulo.

DENMARK

Late Effects of Gastric Resection.—Follow-up studies of patients whose stomachs have been resected for gastric or duodenal ulcers have become more important than ever because of the growing competition between the operative and conservative treatment of such ulcers. The keenness of this competition is emphasized by the growing efficacy of both measures. Improvements of operative technique and of both preoperative and postoperative therapy have greatly reduced the operation risks, but at the same time advances in conservative and medicinal treatment have added greatly to the attractiveness of this alternative. To ascertain what happens to resected cases after a considerable observation period physicians on the staff of the Copenhagen County Hospital in Gentofte have undertaken a follow-up study of the 99 patients (82 men and 17 women) who underwent gastric resection for ulcers in the period 1939-1949. These physicians (Drs. Bent Bjerre, John Engberg, and Ulrik Feldthusen) point out in an article in *Ugeskrift for laeger* for Jan. 8 that the resection was the Billroth's operation in 94 cases, in most of which an entero-anastomosis was established. An attempt was made to resect between two-thirds and three-quarters of the stomach, the indications for operation being very strict, particularly during the first few years of the period under review, with marked invalidism and inability to work in most cases. More than two-thirds of the patients were over the age of 40, with a history of ulcers for 10 years or more.

The follow-up study showed that 7 of these 99 patients had died in connection with the operation, and another 7 had died of various conditions some years after it. Among 81 surviving patients, 18 were completely symptom-free from one and one-half to several years after the operation. Ten patients were still more or less invalids and unfit for work because the operation results were bad. There remained a large intermediate group of 53 patients who, after the same observation period, were subjectively well but objectively rather unsatisfactory, and the quality and quantity of their food had to be regulated with care. Among the 81 patients there were only 3 who frankly declared that they regretted having undergone this operation. On the other hand, most of them spontaneously expressed their gratitude for it. In nearly every case caloric needs could be satisfactorily met by the normal number of meals, and it was exceptional for working capacity not to be improved. In the present publication no reference is made to any original control investigation depending on the follow-up study of cases given conservative treatment only.

MEXICO

Activities of the Institute of Public Health and Tropical Diseases.—The activities and work of the Institute of Public Health and Tropical Diseases, Mexico City, have not always been widely known because they are usually very specialized. On the occasion of the 14th anniversary of the institution its secretary, Dr. Manuel González Rivera, issued an extensive report that reviews the most important investigations and research done since 1939. Following are some of the points of that report.

Laboratory and outside research on whooping cough has been carried out for several years. For four years the value of pertussis vaccine in active immunization has been investigated, as well as determination of the effect of agglutinations of Hemophilus pertussis in blood of vaccinated and nonvaccinated adults. Other investigations included a study on the passage of pertussis antibodies through the placenta and observations on passive immunization with serum of pertussis-immunized subjects.

In cooperation with the International Salmonella Center of Copenhagen, the Salmonella Center of Mexico was organized in 1939. It is dedicated to the study of the bacteriological, medical, and sanitary aspects of salmonellosis and to the study of the disease in humans, particularly children. Salmonellas have been found (in Mexico) to be the cause of many so-called diarrheas, cases of enteritis, and intestinal fevers.

Specific, somatic, and K serums have been prepared that correspond to the 25 groups of the Kauffann-Knyschildt-Vahlne (KKV) antigenic diagnostic diagram. At the same time studies on the antigenic structure of micro-organisms of the coliform group (Escherichia, Aerobacter, Klebsiella, and paracolon) were begun. The "O" group has been determined in 508 cultures (according to the KKV diagram) of coliforms isolated in man, rats, and butter. It has been found that cultures from the intestine of the rat belong to a different serologic group than those of human origin.

Three new species of Salmonella have been described: S. mexicana, S. pensacola (Analmac variety), and S. liceagai (in memory of Dr. Eduardo Liceaga). Several varieties of coliform bacilli that possess Salmonella antigens have also been described. Lately the rat salmonellas of Mexico have been studied. In 1951 the Salmonella and virus laboratory of the institute was designated regional center for the study and classification of salmonellas in all of Central America. The effect of alum on S. typhi and S. paratyphi A and B, was studied to determine the possibility of active immunization against typhoid and paratyphoid with a single dose of paratyphoid vaccine precipitated with alum and also the possibility of producing active immunization in man against the most frequent varieties of pathogenic Salmonella.

The bactericidal and bacteriostatic effect of a new chemical compound, aluminum para-aminobenzene sulfonate (Sulfalumin) on S. typhi, Shigella, Escherichia coli, Staphylococcus aureus, Streptococcus haemolyticus, Brucella abortus, and Br. melitensis was studied, as well as the synergistic action of this drug with penicillin on S. typhi. Other research in the field of brucellosis has been the investigation of agglutination tests in brucellosis patients, and the antigenic and allergic aspects of brucellosis; the differentiation of the type of Brucella by the complement fixation test; culture of Brucella organisms; and forms of treatment of the disease.

Vaccination of white rats against brucellosis was tried. Other work in this field refers to hydrogen sulfide metabolism in Br. melitensis, the role of the spleen in experimental brucellosis, transformation of smooth into rough cultures, determination of nitrogen in different samples of anti-Brucella vaccine, and histopathological studies of human and animal cases of brucellosis.

Research on classic and murine typhus in the laboratory, in clinical cases, and in the field has been related to different aspects of rickettsiosis, preparation of vaccines, immunology and allergy of the disease, agglutination, and complement fixation tests. The distribution of typhus in Mexico has been studied by means of the complement fixation test with murine and classic antigens. The complement fixation test was done with the two typhus rickettsias and with agglutinations of Proteus OX19 in more than 2,500 rats in Mexico City. A low incidence of infected rats was found.

The antigenic fraction (belonging to rickettsias) was investigated in 1,200 cultures of coliform bacilli using the serum of typhus patients. Experiments on fatal infections with Rickettsia prowazekii moorseri in a race of white mice CFCW were done in comparison to the resistance of ordinary white mice. A race was found that is highly susceptible to experimental exanthematous typhus.

A new serologic test for the diagnosis of typhus was described based on the precipitation of antityphus serums by the urine of typhus patients. A modified Weil-Felix reaction and a fast slide method were also described. Experiments on treatment of typhus with serum of convalescent rabbits and other chemical products have been carried out. R. rickettsii was isolated for the first time in Mexico in Choix in the state of Sinaloa in 1943. Later it was found in other parts of Sinaloa, at Sonora and La Laguna.

Continuing the work in recurrent fever, two new outbreaks in Saltillo, Coahuila, and Espíritu Santo, Zacatecas, were localized, where numerous specimens of Ornithodoros turicata were collected and proved to be highly infected with Spirochaetae. In the state of Coahuila a new species of recurrent fever Spirochaeta was found, as were two new species of Ornithodoros, carriers of this disease.

The following work has been done on pinta: morphological study of the Treponema carateum, first under the ordinary microscope and later with the electronic microscope, attempts at culture and inoculation of the Treponema, and a comparative study of the Wassermann, Kahn, and Proske tests in pinta patients. Promising results have been obtained in studies of the therapeutic effect of mapharsen, penicillin, streptomycin, and aureomycin on pinta.

The incidence of intestinal protozoa was studied for the first time in Mexico in relation to infant diarrhea. The first case of infection by Isospora hominis in Mexico was reported, and the epidemiology of Balantidium coli infections was studied.

The characteristics of varieties of Plasmodium vivax from several parts of the country have been studied, verifying the Plasmodium preference for the reticulocytes in the blood as well as in the bone marrow. When P. gallinaceum was used, the possibility of oral infection was confirmed. For the first time in Mexico a methodical study of the Protozoa parasites of wild birds was carried out. The P. juxtanucleare, a chicken parasite in the state of Chiapas, was discovered. The value of chloroguanide (Paludrine) in the treatment of malaria has been assayed. Work on artificial fever was initiated, and study of experimental infection with Spirochaeta turicatae and on malariotherapy for neurosyphilis have been carried out using Mexican species of P. vivax. The institute provides the parasites for the treatment of neurosyphilis to many medical institutions and even to private physicians. An easy method of control of the malaria infection was established.

The geographic distribution of the Culicidae family has been widely studied, especially that of the Anapheles, correcting many errors in the literature in relation to Mexico. A new carrier of the P. gallinaceum was discovered, the Culex quinquefasciatus. The number of Anopheles species described in Mexico has increased considerably, including some described for the first time. On the border between Mexico and Guatemala the following species were found: albimanus, apicicimacula, darlingi, gabaldoni, pseudopunctipennis, punctimacula, strodei, vestitipennis, and Chagasia banthanus.

Epidemiological data have been obtained, and some work has been done on leishmaniasis americana in Mexico. The biology and types of cultures have been studied, and a comparative cytological and immunologic study between the Mexican and South American species is being carried out.

Explorations continue in order to detect new cases of Chagas disease; Trypanosoma lewisi in rats has been investigated; Schizotripanum cruzi was found in one rat in Mexico City; two species of triatomas were found to be infested with Trypanosoma cruzi; and experimental infection of triatomas with large and small numbers of trypanosomas has been tried. Experiments on the transmission of Trypanosoma cruzi in several species of Ornithodoros have also been performed. The existence of Triatoma protacta woodi and Triatoma gerstaeckeri in Mexico was discovered; attempts were made at crossmatching Triatoma hegneri with Triatoma dimidiata and the collection of triatomides continues in different parts of the country in order to determine what species exist in Mexico and their geographic distribution. Similar studies are in process in relation to Ornithodorus species, specially Ornithodorus furcosus. A new species of Ornithodorus was discovered and was named O. drigesi.

The existence of microfilaria ozzardi in Mexico was proved, and an outbreak in the state of Campeche is being studied. Hetrazan (1-diethylcarbamyl-4-methyl piperazine dihydrogen citrate) was tried in patients with this filariasis. It seems to have no effect on such filaria.

The effect of Hetrazan in onchocercosis was studied experimentally. In a group of patients observed for over a year, it was found that the drug improved noticeably the ocular disturbances and reduced the number of microfilarias.

Thousands of Simulium flies have been identified. Sixty new species have been found, with three genera and eight subgenera. Five of the new species were found in the onchocercosic zone of Chiapas and Oaxaca. Many species of larvae were studied and codified. The material already known was also reviewed and classified. The transmission of Onchocerca volvulus by the Simulium mangabeirai was studied, and a sample of Simulium exiguun was found to be infected.

Many classifications of Simulium flies have been made (by the institute) not only in Mexico but also in the British Museum, the National Health Institute of Caracas, Venezuela, the University of California, the School of Tropical Medicine of San Juan, Puerto Rico, and other institutions. Also in this matters the institute receives consultation and has an exchange with institutions or persons from Canada, the United States, Brazil, Colombia, Guatemala, and French Guiana.

Since the foundation of the institute, work has been done constantly on helminthology, investigating the incidence of the different parasites in man and animals. Much data on cisticercosis has been collected.

Investigations on oxyuriasis have been carried out in thousands of children and adults in Mexico City and other parts of the country. The presence of Enterobius vermicularis has been investigated in the perianal and vulvar regions. In many cases other helminthic eggs have been found. The importance of repeated stool examinations has been emphasized, and a comparative study between the Hall and Graham techniques for the diagnosis of oxyguriasis has been done.

Trichinosis in muscles was investigated by the digestion method in 1,000 human diaphragms in Mexico City and in another 1,000 subjects by the Bachman test.

The institute has held a very important place in the field of mycology. Since the beginning the mycology laboratory has tried to determine which of the mycoses exist in Mexico. The Actinomyces of the actinomycotic mycetoma were studied experimentally in laboratory animals and under the electronic microscope. Cultures were made in chicken embryos. It was determined which fungi infected humans and which laboratory animals are the best for experimental infection.

It was found that 90% of cases of actinomycosis in Mexico are caused by Nocardia mexicana. Less frequent are Actinomyces madurae and A. pelletieri. In study of Actinomyces under the electronic microscope, it was found that the acid-fast Actinomyces have a thin capsule similar to that of the Mycobacterium tuberculosis. By cultures in chick embryos, frank differences were found between the acid-fast and non-acid-fast Actinomyces. The work carried out suggests that the Actinomyces mexicanus is the same as the Actinomyces braziliensis, the most important species in Brazil. Maduromycotic mycetoma has also been found in Mexico, although it is rare in comparison to actinomycosis. It is caused by a Cephalosporium.

Since 1941 the existence of chromoblastomycosis in Mexico was indicated, after culture of Hormodendrum pedrosoi in a case described by the institute as probably a case of dermatitis verrucosa.

In a series of publications, the dermatophytes causing tinea of the scalp, skin, and nails were described, identifying species epilans, sabourandi, and sulfureum with T. tonsurans.

Sporotrichosis has also been studied, and an antigen for diagnosis has been elaborated from the hydrocarbonated fraction of the Sporotrichum sckenkii; this antigen used for intradermal tests substitutes the culture for the diagnosis of sporotrichosis. This test has been adopted in the majority of the medical institutions in Mexico and some in the United States.

Several antagonists have been isolated for the most important pathogenic fungi: Cryptococcus neoformas, Blastomyces dermatitides, and Nocardia brasiliensis. Means of utilizing these species like antibiotic substances against mycosis are being studied. It was found that streptomycin is less efficient than penicillin in the treatment of infections caused by Actinomyces bovis. Actidione showed an inhibiting effect on yeast-like fungi, and is therefore useful in the treatment of cryptococcosis and moniliasis. Among the chemical products studied, a combination of sulfanilamides and copper showed a specific effect against N. brasiliensis, the agent causing actinomycotic mycetoma in Mexico, for which no treatment was known.

NORWAY

Tuberculosis in the Armed Services.—Reports on tuberculosis in the services continue to show how difficult it is to avoid an outbreak of tuberculosis in men on active duty, however impressive modern methods for combating tuberculosis may appear on paper. In an article on tuberculosis in the fighting services in 1949-1950, published in the organ of the Norwegian Medical Association, *Tidsskrift for den norske laegeforening,* for May 1, 1953, Dr. Herman Höst admits that during the postwar years tuberculosis has proved to be the most serious medical problem confronting the authorities. During the five year period 1947-1952, a total of 3,046 servicemen received compensation for disease contracted in the service, tuberculosis being responsible in 1,337 of these cases (43.9%). But it is encouraging to note that expenditure in this field has shown a sharp decline, for about 1,100,000 kroner were paid to 335 patients with tuberculosis in the budget year 1947-1948, whereas for the budget year 1951-1952 only about 440,000 kroner were distributed among 120 such patients. Since March, 1951, provision has been made for the tuberculin testing, before they are called up, of all who are liable for military service, the background of this measure being the law of 1947 providing for tuberculin testing and compulsory vaccination with BCG. Exemption from such vaccination can, however, be claimed by persons who continue to be tuberculin-negative after repeated vaccinations. During service in the armed forces mass radiography is repeated every third month, negative reactors being retested with tuberculin at the same intervals. Provision is also made for a search for tuberculosis in the home environment of the men found to be tuberculous while on active duty.

In his discussion of the merits of the various diagnostic tests of tuberculosis, Dr. Höst points out the shortcomings of both mass radiography and an ordinary clinical examination. Faith in the former is apt to render the latter somewhat perfunctory, and the former certainly requires technical skill and first-class equipment. Among 680 men found to be tuberculosis-suspect, there were as many as 141 who proved on closer observation to be nontuberculous, nonspecific pulmonary infiltrations being the commonest source of error. A leading article in the same number of the journal stresses the importance of linking up the different tuberculosis tests in such a way that their findings can be made available promptly and translated into action. It is urged that BCG vaccination should be followed by tuberculin control long before recruits are called up.

Care of Mental Defectives.—Substantial advances have been made in Norway with regard to the care of mental defectives since the end of World War II, when there were only three establishments for their care, with a total of 495 beds. By March 1, 1952, this number had risen to 1,115 distributed over 23 establishments approved officially. These establishments are in two cases state owned, with 446 beds, and in two others municipal owned, with 70 beds, the remainder being owned by voluntary health organizations or private persons. This combination of state and private activities in the approach of a social problem is typical of what happens in Norway in many other spheres, and in its planning for the future the government makes a point of encouraging private enterprise as a much valued corollary to its own doings. In the spring of 1952 the Norwegian Parliament endorsed a plan devised by the Department for Social Affairs for dealing with mental defectives. The number of low grade mental defectives incapable of benefiting from special educational facilities for mental defectives of higher grades can hardly be under 10,000 to 11,000. It is calculated that 6,500 beds are needed in homes for mental defectives, at the rate of about 2 per 1,000 of the population, but this figure must at present be regarded as out of reach, and the government's plan provides for only 5,200 beds. These are to be filled as rationally as possible, the mental defectives who cannot be accommodated in these beds being provided for in private homes and families, day homes, or the like. The 5,200 beds will, for the most part, be distributed among seven large regional establishments, each with several hundred beds and catering to communities with a population of about 500,000 to 600,000. Each of these regional establishments is to be composed of a series of smaller units devoted to some special function. These establishments are to be responsible for the care not only of mental defectives within their gates but also of those in smaller establishments in the neighborhood, including private homes and families. These subsidiary centers will include homes for the aged, a tuberculosis department, and quarters for children under 10. Since the war the government has concentrated on extending and modernizing its two original large establishments, on the assumption that the provision of smaller units such as day homes belongs to the sphere of private enterprise. There is much to be said in favor of more or less autonomous units whose administration provides scope for local enterprise.

Deaths of Dr. Karen Margrethe Simonsen Eek and Dr. Axel Scheel.—Born in Denmark on June 5, 1903, Dr. Simonsen received her medical training in Copenhagen and spent the first three years of her medical career in Danish provincial hospitals. Mental disease in children attracted her attention early, and her thesis for the degree of doctor of medicine was largely concerned with the psychic handicap of children reared in institutions where cleanliness and an adequate supply of vitamins do not compensate for a lack of personal care and love. Her studies abroad, including the United States, were largely concerned with the psychiatric problems of adults and children, but she did not neglect to equip herself with experience in somatic disease. Her appointments at the Rigshospital in Copenhagen led up to her becoming first assistant physician to the newly created children's wing of the psychiatric department. To further her experience, she began private practice in child psychiatry in Copenhagen. A few months later she was invited to take charge of the recently created department of child psychiatry at the Rikshospital in Oslo. Here she concentrated her efforts, determined to live and work as a native of the country of her adoption. In the summer of 1951, she married the Norwegian radiologist Dr. Sigurd Eek. She also adopted two boys. Her singularly serene personality created an atmosphere in her department that children and even adults were quick to sense and appreciate, and the cordiality of her staff reflected the spirit infused by this quiet, middle-aged woman whose death on May 13, 1953, means an irreparable loss to child psychiatry in Norway.

Dr. Axel Scheel, who died in May, 1953, at the age of 47 after about a half year's illness, came of medical stock, both his father and his grandfather having made their mark as physicians in Norway. His father was responsible, with Dr. Heimbeck, for the introduction of BCG vaccination in Norway. His son Axel qualified as a physician in 1932. After holding various hospital appointments, he began in 1936 to specialize as a radiologist, and from that time on he published several important works on his subject. Like many other patriotic Norwegians he worked abroad during the German occupation of Norway. From 1946 to 1950 he was in charge of the radiological department of the Aker's Hospital, and in 1950 he took charge of the radiological department of the Norwegian Radium Hospital. His doctorate thesis in 1946 was concerned with tuberculosis of the bones.

SWEDEN

Syphilis in Would-Be Blood Donors.—In the spring of 1952 the Swedish Red Cross organized a drive for blood donors in the County of Malmöhus, with the result that 5,908 new donors were registered. Among them were 4,009 who were willing to serve not only in wartime but also in peacetime. The typing of these prospective donors was undertaken at the blood donor center of the Malmö Hospital, while the pathological-bacteriological department of the same hospital undertook the search for cases of syphilis. In *Svenska läkartidningen* for April 17, 1953, Dr. Bengt Willert and Dr. Sten Winblad have published their findings of 5,668 would-be donors and their experiences with regard to the elimination of persons with syphilis from among them. After the first 460 examinations had been carried out with Meinicke's reagent for screen testing, it became evident that this was not enough by itself. In addition to this test, a complement fixation test with cardiolipin as antigen was carried out, and, in doubtful cases, multiple tests were carried out next day with Meinicke's, Kahn's, and complement fixation tests. Altogether, 5,636 samples of blood were examined for syphilis. A slight Meinicke reaction was observed in 145 cases and a definitely positive Meinicke reaction in 54 cases. Thirteen persons had a positive Wassermann reaction, but there were only eight cases (1.4 per thousand) in which the reaction was positive to all three tests, Wassermann, Meinicke, and Kahn. There were five cases in which the Wassermann test was positive, while the other tests were negative. Dr. Willert and Dr. Winblad have come to the conclusion that in searching for syphilis among prospective blood donors, screening with only one test is not sufficient for the purpose. At least two tests are needed, and one of them should be a complement fixation test according to the Wassermann technique.

Licorice Therapy in Cases of Gastric Ulcer.—At the surgical department of the Sollefteå Hospital large doses of licorice have been given to a score of patients suffering from gastric and duodenal ulcer. Reporting on this treatment in *Svenska läkartidningen* for April 10, 1953, Dr. B. Gylling points out that the introduction of licorice therapy of gastric ulcer comes from a small town in Holland, where a patent medicine containing licorice became such a success that licorice came to be seriously studied as a remedy for gastric ulcer. Dr. Gylling's patients were, for the most part, so ill that surgery was indicated, and the drug was given (about 55 gm. daily) finely powdered and suspended in water, one mouthful every hour of the day for one to three weeks. The patients with duodenal ulcer did not respond as quickly to this treatment as those with gastric ulcer, who usually showed rapid improvement. But some of the patients did not tolerate this treatment well and requested its discontinuation, having experienced no relief, Dr. Gylling writes: "We have been unable to discover any remarkable healing of an ulcer in comparison with the time taken for an ordinary ulcer cure to effect recovery."

One of Dr. Gylling's patients was remarkably instructive with regard to her reaction from time to time to this therapy. She was a nurse, aged 52, with a history of gastric symptoms for more than 15 years and radiologically demonstrable gastric ulcer. Her symptoms vanished after only one day's treatment, and she was well satisfied with the response to it during the next five to six weeks, after which headache and severe edema of the face developed. These symptoms disappeared promptly when the drug was withheld, but the ulcer symptoms returned two months later. The licorice therapy was resumed, the ulcer symptoms disappeared, and a week later the edema and headache returned. The same cycle of reactions followed.

TURKEY

Recovery After Pneumonectomy for Lung Cancer.—In *Anadolu Kliniği*, Istanbul periodical, Recai Ergüder, professor of the second surgery clinic of the Gülhane Military Medical Academy Hospital, and his senior assistant, Dr. Orhan Bumin, described the clinical manifestations and diagnostic procedures of carcinoma of the lung. After a brief description of the first case in which surgical treatment has been successful in Turkey, they discussed the technique of pneumonectomy, the operative mortality, and the five year recovery rate. The patient, a 50-year-old military officer, had influenza for two weeks but had not fully recovered when he returned to duty. After three days the cough increased, pain developed in the back, his temperature rose to 39 C, and the patient was admitted to the hospital. He was weak, had no appetite, and had an audible wheezing cough of 20 days' duration. His father had died of cancer of the tongue. The patient himself had not had any serious illness. For 30 years he had smoked a pack of cigarettes daily, but he had never used alcohol. From time to time he had had mild bronchitis and, as a result of his smoking, a cough with expectoration in the mornings. On admission to the hospital the patient had an elevation of temperature that continued for 20 days, reaching 39.8 C. Results of urinalysis and the blood chemistry were normal. The leukocyte count was 22,000, and the erythrocyte sedimentation rate during the first day was 45 mm. per hour and subsequently attained 123 mm. A histoplasmin test and sputum test for tuberculosis bacilli were negative. Clinical and radiological examination and bronchoscopy revealed vegetation and an easily bleeding tumor on the bronchi leading to the upper lobe of the left lung. Histological examination of the material obtained by bronchial aspiration confirmed the diagnosis of cancer. In preparation for the operation the patient was given penicillin and vitamins B and C. During the operation the patient was transfused with 2,000 cc. of blood. Nitrous oxide, ether, and oxygen anesthesia was used. After pneumonectomy had been performed, the left pleural cavity was flushed with penicillin and streptomycin and, as recommended by Bailey of the United States, a temporary tracheotomy was performed to insure proper aspiration of the bronchi. The patient was given oxygen continuously. On the third day the tracheotomy tube was removed and the incision closed. Several roentgenograms made three days after the operation revealed that over the center of the mediastinum fluid had collected in the left pleural cavity and that the diaphragm had risen. According to the report Prof. N. Eranil of the pathology department of the Ankara University medical faculty, the tumor was an oat cell carcinoma. The patient recovered within two months and returned to active duty.

Leprosy in Afghanistan.—In *Klinik*, Bursa Medical Society periodical, Prof. Halil Gürün, a Turkish physician and graduate of Istanbul University, who was in the service of the Afghanistan government for four years as chief of the Kabul Medical School department of dermatology, reports that leprosy (Hansen's disease) in that country is endemic and manifestly increasing. In the author's estimation there are 25,000 to 30,000 persons with leprosy in that country. All are without medical care and resort to home remedies as best as they can. Dr. Halil Gürün reports that 22 (0.16%) of 12,389 patients examined during 1949 at the dermatology outpatient clinic of the Kabul Medical School had leprosy. In 1950, 32 (0.17%) of 19,504 patients, in 1951, 57 (0.25%) of 22,419 patients, and in the first six months of 1952, 142 (0.43%) of 13,509 patients had leprosy. The majority of the patients had lepromas on the face, the extremities, the abdomen, and the thorax. Testicular and laryngeal lepromas, extreme malformation and perforation of the buccal and nasal cavities, and mutilation of the hands and feet have been observed. In all patients Hansen's bacilli were present in tissue and serologic tests were positive.

Besides persons from Kabul itself, patients had come from the villages at the border of Turkistan, Pakistan, and central and southern Afghanistan. There have been no patients from the far southwest regions. Of the 163 patients who in turn occupied the seven beds set aside for leprosy patients at the Kabul Medical School, the only place where chaulmoogra oil and sulfonamides are available, 6 were women and 7 were children. Three of the children were girls 7 to 11 years old, and four were boys 9 to 11 years old. The majority of the men were of military age. On discharge the patients were given disulfanilamide (Disulon) tablets. The clinical types of leprosy encountered among the 163 patients were the anesthetic in 54, mixed in 48, tubercular in 27, lepromatous in 29, and mutilating lepromatous in 5.

In August, 1952, the author accompanied Dr. S. Christiansen on a short tour of investigation sponsored by the World Health Organization. A mobile clinic and laboratory was opened in five villages in Hazaracat, a region long famous for its leper colonies. Of 314 persons examined, 2 had lepromatous leprosy, 3 had maculoanesthetic leprosy, and 6 had cicatrized atrophy, anesthetic thermoanalgesic plaques, polyadenopathy, and nasal mucosa ulcerations. Investigation at the Kabul laboratory revealed that 13 patients had Hansen's bacilli in tissue specimens.

After discussing the pitiful plight of persons with leprosy, the author concludes that ignorance, dire poverty, superstition, lack of medical care and medicaments, the inability of the government to remedy the situation because of insufficient medical personnel, the absence of funds for medicaments and an insufficient health budget, which is not even enough to contend with tuberculosis, malaria, syphilis, trachoma and parasitic diseases, and the seasonal epidemic are mainly responsible for the regrettable conditions. Outside assistance is urgently needed.

Spontaneous Rupture of Uterus.—Also in *Klinik* Dr. Arif Sözen, chief of the Bursa Maternity Hospital and his associate, Dr. Mehmet Yurdabag, reported a case of spontaneous rupture of the uterus. The 38-year-old patient had had seven normal deliveries. Fifteen hours before the eighth delivery labor pains began, after seven hours the hand of the baby presented itself, and an hour later the labor pains ceased. When extreme pain in the abdomen followed, the patient was taken to the maternity hospital. On admission the patient was weak and pale, had a temperature of 36.7 C, and a pulse rate of 104. The abdomen was painful and swollen, on the left side the fetus was palpable, and on the right side the contractions of the uterus were evident. Then the right arm and shoulder and the umbilical cord presented itself, and there was a dark red secretion from the vagina. A cesarean section was performed, and the child was found among the intestines. The rupture, which had occurred on the left side of the uterus, was 8 cm. long, extending from the parametrium to the vagina. It was sutured and a supravaginal hysterectomy was performed. The abdomen was flushed with 2 million units of penicillin. For five days the patient was given 1,600,000 units of penicillin injections and 1 gm. of streptomycin. Recovery after two weeks was uneventful. Among the 5,200 deliveries at the Bursa Maternity Hospital, 16 (0.3%) uterine ruptures have been observed. According to the western medical literature, the incidence is from 0.12 to 0.3%.

Report on Leukemia.—In *Sağlik Dergisi,* the official periodical of the Ministry of Health and Social Assistance, Dr. Ihsan Aksan, chief of the Ankara General Hospital medical department, and his associate, Dr. Naci Arun, have published a report on 460 cases of blood diseases seen during a 10 year period. Of the 460 patients, 229 had hypochromic anemia, 66 splenic anemia, 60 hyperchromic anemia, 31 chronic myeloid leukemia, 18 hemorrhagic diathesis, 10 secondary thrombocytopenia, 9 chronic lymphoid leukemia, 7 lymphogranulomatosis, 6 acute myeloid leukemia, 6 acute lymphoid leukemia, 6 Banti's disease, 5 hemolytic anemia, 2 polcythemia, and 1 case each of essential thrombocytopenia, capillary toxicosis, pernicious anemia, hemophilic anemia, and achroacytosis (Mikulicz's disease). All the patients were males, and their ages ranged from 10 to over 60 years. Thirty-six had had malaria. Seven patients had typhoid, five pneumonia, three rheumatism, three icterus, one pleurisy, and one dysentery. None of the patients had had tuberculosis. In none of the cases was there a hereditary factor.

Thirty-nine patients had chronic and 13 acute leukemia. Of these, 34 patients had myeloid leukemia and 18 had lymphoid leukemia. The onset of acute cases resembled that of septicemia, with a temperature of 37.5 to 40 C, chills, aesthenia, sudden pallor, and in acute attacks hemorrhagic diathesis. The blood pressure of the 52 patients with leukemia was normal or subnormal. The sedimentation rate accelerated as anemia became more pronounced or other factors entered into the picture. The blood of all patients had a very high uric acid content. Because of the high protein metabolism, the basal metabolism was high in most of the patients with advanced myeloid and lymphoid leukemia, this was not so apparent in patients with aleukemia. Urinalysis revealed traces of albumin and a high uric acid content in all cases. When thrombocytes neared the danger zone a tendency to hemorrhage was observed. In some cases the cause of hemolytic anemia was not quite evident. In a great many cases, especially when the spleen was involved, the cause seemed to be the interaction of the erythroblastic reaction, erythropoiesis, erythrophagic histiocytes, and reticuloendothelial system.

During the initial stage in acute leukemia, the number of leukocytes per cubic millimeter was generally below 100,000; in four cases it was 3,000 to 10,000 and in five cases 38,000 to 76,000. In chronic leukemia the number of leukocytes per cubic millimeter was 100,000 to 800,000, with the whole series of myelocytes present. In acute cases mononuclear monocytes predominated, and in chronic cases all types of myeloblasts were found. Though the relation of the number of leukocytes to the severity or the duration of the disease was not definitely established, it was observed that in the final stages of a leukemia there was generally an increase in leukocytes. Predominance of mature forms indicated recovery.

A 19-year-old patient with a temperature of 38 C had been ill with rheumatism for three months. The pain in the joints had not subsided, and he perspired profusely during the night. Examination on his admission to the hospital revealed a painful and swollen left knee, enlarged lymph nodes on both sides of the neck, the clavicles, and axillas, a palpable spleen, and chronic tonsillitis. The patient had a temperature of 37.6 C, the pulse rate was 100, the sedimentation rate 18 to 40 mm., and the blood pressure 120/80 mm. Hg. There were 46,000 thrombocytes and 1% reticulocytes. The blood contained 8.66 mg. of total protein per 100 cc., with 4.88 mg. of albumin and 3.92 mg. of globulin. The blood examination revealed a hemoglobin level 70% of normal, 3 million red blood cells, and 10,000 white blood cells, 13% myeloblasts, 12% polymorphonuclears, 19% immature forms, and 56% lymphocytes. On the 9th day further enlargement of the spleen, the liver, and the lymph nodes became evident, and on the 11th day there was enlargement of the inguinal lymph nodes. The patient was given urethane in doses of 3 gm. daily for a total of in all 108 gm., but his condition did not improve and he died three months later. Twelve patients with myeloid and three patients with lymphoid leukemia were given urethane therapy. In eight of these patients the spleen and liver considerably decreased in size and the lymph nodes softened. One patient recovered so completely that he was inducted into the army on his discharge.

Antibiotic Effect of Chloramphenicol and Oxytetracycline.—In *Sağlik Dergisi,* journal of hygiene and the periodical of the Ministry of Health and Social Assistance, Dr. Mesut Okan, bacteriologist of Istanbul University Ziya Gün Foundation Research Institute, has published the results of his comparative investigation of the antibiotic effect of chloramphenicol (Chloromycetin) and oxytetracycline (Terramycin) on 15 saprophytic and pathogenic micro-organisms. The organisms included Staphylococcus aureus hemolyticus, Streptococcus longus hemolyticus, pneumococcus, Salmonella typhosus, S. paratyphi A, S. paratyphi B, Shigella paradysenteriae Flexner, Brucella melitensis, Bacillus anthracis, Escherichia coli, Aerobacter aerogenes, Proteus vulgaris, Pseudomonas aeruginosa, Candida albicans, and B. subtilis. A 1 cc. dilution of 5 and 2.5 mg. of chloramphenicol and oxytetracycline was used, and the result was observed for five hours. Except on the pneumococcus organism and the anthrax bacillus, chloramphenicol was more effective than oxytetracycline. Chloramphenicol proved especially effective on Eberth's bacillus (S. typhosa), but had very little effect on the paratyphoid B bacillus. On anthrax bacillus oxytetracycline proved very effective after only a few hours, but only half of the pneumococcus bacilli were dead after five hours. Whether 2.5 or 5 mg. of the antibiotic was used did not affect the result appreciably. When after 48 hours cultures were made on the part of the dish that had remained sterile, neither dead nor living organisms were obtained and new cultures also proved negative, indicating that the effect of these two antibiotics are bactericidal rather than bacteriostatic. When chloramphenicol was further diluted, the bactericidal result approached that of oxytetracycline.

THE LEISURE CORNER

MEDICAL STAMPS

In 1947 the Post Office Department of the United States issued a three cent stamp, reproducing Samuel Luke Fildes' "The Doctor," to commemorate the work of physicians as part of the celebration of the birth of the American Medical Association 100 years before. Recognition at this time of the physician's role in society, at least postagewise, was due in great measure to the growing awareness in many countries that medical men, medical events, and medical institutions are often fully as important as kings, queens, presidents, dictators, and generals. Actually, the number of postage stamps now commemorating medical and allied scientific achievements is so large that even the most ardent collector may be startled by the proportions of the field of medical philately. Because it is so extensive only a few aspects can be touched on in this article.

Sooner or later medical philately, if its pursuit is not to be haphazard and superficial, requires of the hobbyist a knowledge of medical history. The reason for this is that medical philately deals not only with medical portraiture, medical events, and medical mythology but also with medical buildings and institutions, stamps depicting diseases and medical botany, the Caduceus, the Red Cross, and Health Postal Taxes. In reality, there is as much room for specialization in medical philately as there is in the practice of medicine. For beginners a collection of medical portraits is probably the easiest to acquire, since many physicians have been commemorated both for their work in medicine and for their contributions and achievements in nonmedical fields.

There seems to have been no planned trend in the use of physicians' heads on postage stamps. In 1928, a famous physician's features greeted the addressee of almost every letter from Holland. The features were those of Hermann Boerhaave, who was born in 1668, and who became the first great clinical or "bedside" teacher. Until the 17th century there had been no systematic clinical teaching and all of the universities conferred medical degrees on the basis of a spoken disputation. Contact with patients was not required of medical novitiates and practitioners until Boerhaave instituted clinical teaching in 1701. In 1935 the Netherlands issued a six cent stamp depicting Frans Cornelis Donder, the famous Dutch ophthalmologist who was a notable contributor to physiological optics during the past century, introducing the use of prismatic and cylindrical lenses for the correction of certain types of eye defects and offering the first exact definitions of myopia and presbyopia.

In 1937 Austria paid homage to the old Vienna School of Medicine by placing the portraits of nine famous 19th century physicians on a series of stamps. These included Theodor Billroth, who was the founder of modern visceral surgery; Karl von Rokitansky, who performed more than 30,000 autopsies during his lifetime and who made voluminous contributions to the field of pathology; Ferdinand von Hebra, founder of the histological school of dermatology; Leopold Auenbrugger, discoverer of percussion as a diagnostic procedure; Joseph Skoda, whose name is given to the rale found in pneumonia; Carl Ferdinand von Arlt, whose treatises helped make ophthalmology an independent specialty; Theodor Meynert, an eminent neurologist and psychiatrist who made many investigations on the anatomy and physiology of the brain; Josef Hyrtl, who was the first great teacher of topographic and regional anatomy; and, finally, Gerhard van Swieten, founder of the old Vienna School of Medicine.

The likeness of Ignaz Philipp Semmelweis appeared on a Hungarian stamp in 1932 in honor of his epochal discovery of the value of antisepsis in obstetrics. This theory first met with considerable derision, but it was eventually accepted, enabling it to revolutionize the practice of obstetrics. Another brilliant investigator, whose portrait was reproduced on a postage stamp by Czechoslovakia in 1937 on the occasion of the 150th anniversary of his birth, was Johannes Evangelista Purkinje. He observed that fields of different color and equal brightness become unequally bright when illumination is decreased in brightness. To the layman, however, he is of interest chiefly because he established the permanent character of the fingerprint. The 19th century is known for the investigations of various pathologists, notably those of Louis Pasteur. In 1922, the 100th anniversary of the birth of Pasteur, the French government decreed that the three most used denominations of stamps would bear his profile, and this practice was continued for 10 years. Again, in 1936, a special set of stamps was issued to raise funds for impoverished French intellectuals, one of the stamps showing a three-quarter portrait of Pasteur holding a test tube.

Although some nations have dedicated postage stamps to physicians because of their medical accomplishments, others have memorialized them for achievement in other spheres of activity. In this connection, Germany has commemorated Johann Wolfgang von Goethe, the great 18th century poet who became interested in evolution and who was the first to use the term morphology, and Friedrich von Schiller, who spent so much time writing poetry while he was an army surgeon that he was arrested and condemned to write only medical treatises. Schiller escaped medicine by running off, thereafter devoting himself entirely to poetry, a field in which he acquired immortal fame.

Among "political truants" from medicine are physicians whose likenesses on stamps point to their ability as presidents of nations, high officials in government, or martyrs in the fight for freedom. To name a few, there are such notable American figures as William Henry Harrison, ninth president of the United States, who was a onetime pupil of Benjamin Rush, and Manasseh Cutler, honored on a United States stamp not so much because he was a good physician but because he was a good diplomat, lawyer, and minister of the gospel. Their appearances on postage stamps took place in 1938 and in 1937 respectively. Another medicopolitical figure, who once practiced medicine in New York and who later dominated French politics during World War I, was George Clemenceau, and still another was Sun Yat-sen, who became the first provisional president of China.

The medical history of the United States is replete with names of physicians who have achieved world fame. By means of the postage stamp knowledge of their accomplishments has been spread throughout the land. Among these doctors are Walter Reed, who headed a mission that eradicated yellow fever in the United States and West Indies, if not throughout the entire world; William C. Gorgas, who made the building of the Panama Canal feasible through the conquest of malaria and yellow fever; and Crawford W. Long for his pioneering with ether as an anesthetic. At the present time American postal authorities are believed to be considering a series of stamps honoring distinguished American medical men. Although as yet there is no intimation from official sources as to the time the stamps will appear or if they will be issued at all, the physicians nominated for the proposed series include, among others, William Beaumont, whose investigations on the digestive process have been hailed by some as America's greatest contribution to experimental physiology; Joseph Goldberger, a pioneer in vitamin research and responsible for the discovery that pellagra is caused by diet deficiencies; William Stewart Halsted, first surgeon to use rubber gloves and a pioneer in the use of local anesthesia; Oliver Wendell Holmes, poet, essayist and critic, who was one of the first to recognize the contagious nature of puerperal fever; William Henry Welch, pathologist and bacteriologist who helped found the Johns Hopkins Medical School; William Osler, whose textbook on medicine is still a standard; Ephraim McDowell, who performed the first ovariotomy; James Marion Sims, father of gynecology; and Howard T. Ricketts, the pathologist who demonstrated the transmission of Rocky Mountain spotted fever by ticks and typhus by lice.

One of the earliest European countries to recognize the achievements of the nursing profession philatelically was Romania. In 1906 a stamp appeared that showed Queen Elizabeth as a nurse administering to a wounded soldier. The message beneath the Queen's handwriting read, "Wounds are dressed and tears are wiped away." In 1925, stamps issued by Luxembourg depicted a nurse applying medication to the brow of an obviously appreciative male patient. In 1921, Jugoslavia issued semipostal stamps for the benefit of invalid soldiers. One of these portrayed a nurse giving succor to a wounded soldier. On the occasion of the 75th anniversary of the Red Cross movement, a number of countries commemorated the event in stamps. France and Belgium included in their commemorative set a portrait of Florence Nightingale, founder of modern nursing as we know it today.

For the avid medical philatelist there are a number of specialties coming under the general heading "Medical Stamps" that are sufficiently complicated to challenge his ingenuity. Thus, for example, the specialty of the doctor portrayed can be used to establish subclassifications of groups such as surgeons, internists, ophthalmologists, histologists, and bacteriologists. Moreover, a number of geographical features have been named for the medical great, and medical events have been the basis for several commemorative issues. Then, there are stamps dealing with medical mythology, medical buildings and sanitoriums, medical botany and pharmacology, and diseases. All in all, the joys of medical philately are endless, providing both pleasure and education in medical history for those who are drawn to the world of stamps.

BUREAU OF MEDICAL ECONOMIC RESEARCH

For several years the Bureau of Medical Economic Research has presented in The Journal *an annual summary of the Consumers' Price Index and the medical care portions thereof. Since the Bureau of Labor Statistics of the United States Department of Labor is in the process of shifting to a new and enlarged price index, this article should be regarded as the transition or "changeover" article in this series. As such, this article is of unusual value to physicians interested in the entire series of articles.*—Ed.

OLD AND NEW BASE PERIODS FOR MEDICAL CARE PRICE INDEXES

Frank G. Dickinson, Ph.D.

During World War I, a price index for consumers was developed by the Bureau of Labor Statistics of the United States Department of Labor to provide data that could be used in making wartime wage adjustments. In 1940, the Consumers' Price Index, sometimes erroneously called the "Cost-of-Living" Index, was revised, the coverage was broadened, and 1935-1939 = 100 was selected as the base period. The historic purpose of the Index has been to present a summary measure of price changes for consumers in the United States. Over the years, it has been an important tool for analyzing economic trends, and it has been used widely in recent years in collective bargaining agreements as a basis for automatic wage adjustments.

This Index is being overhauled again. A brief description of the three indexes currently available, in the chronological order of their development, will help to explain the transition. After this transition period is completed only the revised index will be published regularly.

Unadjusted Index.—This index was used before the adjusted series was developed. Its base period is 1935-1939, and all the breakdowns are available for the period from 1940 to June, 1953, although final annual averages for the sections are not yet available for 1952. This index was discontinued in June, 1953, and would have been discontinued in December, 1952, if a presidential directive requesting that it be continued for six more months had not been issued.

Adjusted Index.—This index is available for 1952 on both the old base period, 1935-1939, and the new base period, 1947-1949. It was originally computed only for 1951 and 1952 on the old base period. Later it was extended back to cover 1950 and, in fact, has been extended back to 1940; the breakdowns were carried back to 1940 only for rent and transportation. The differences between the adjusted and unadjusted indexes for any month, quarter, or year are very small except in some sections of the Index, e. g., transportation. Unfortunately, the annual indexes for 1952 have not been published for the sections of this Index, although the average for the entire Index has been published.

Revised Index.—This index started in 1953 on the 1947-1949 base only. (We shall avoid the temptation to call this the "new index" because the term "revised" is preferred.) Approximately 100 additional items are covered. For some months to come only one composite figure will be available for medical care, but eventually indexes for each of the medical care items will be published when this busy transition period for the staff of the Bureau of Labor Statistics ends.

Our major emphasis is on the effects of shifting the base period from 1935-1939 to 1947-1949, using the adjusted indexes. No figures for the revised indexes will be presented, and the only use of the unadjusted indexes (on the old base) will be in computing averages for the breakdowns for the new base period, 1947-1949. As noted already, after this transition period is over, only the revised index will be published.

Table 1.—*Consumers' Price Index and Indexes for Medical Care for Moderate-Income Families in Large Cities for 1951-1952 (1935-1939 = 100)*

Adjusted Indexes	1950 (1)	1951 (2)	1952 (3)

II. Prescriptions and drugs	124.8	128.4	129.7
A. Prescriptions	140.7	147.7	149.6

* All other indexes in this column were computed by the author from published quarterly indexes.
† December, 1950 = 100.

1952 LEVELS

In 1952, the Consumers' Price Index (adjusted) rose 4.1 points, from 185.6 in 1951 to a peak of 189.7. The index of medical care and drugs, which is a small portion of the entire Index, rose from 155.0 to 164.2, a gain of 9.2 points. Although the medical care portion of the Consumers' Price Index rose twice as many points as the entire Index during 1952, the medical care portion was still 25.5 points lower (on the old base). Moreover, the index of medical care and drug prices increased 64.2% over that of the base period 1935-1939, while the entire Index increased 89.7%.

What changes have occurred in the indexes of the individual medical care items? As is shown in table 1, the index of medical care, excluding drugs, was 171.8 in 1952 (row I), and the index of prescriptions and drugs was 129.7 (row II). The index of physicians' fees (general practitioner, surgeon, and specialist) was 152.2 (row IA); general practitioners' fees, 152.4, and surgeons' and specialists' fees, 150.4. With the exception of prescriptions and drugs, 129.7, optometrists' fees, 136.4, and dentists' fees, 163.8, all the items of the 1952 medical care index increased more points above 1951 than the entire Consumers' Price Index. The rise in the entire Consumers' Price Index from 1950 to 1952, 17.8 points, was larger, however, than the rise in the medical care index, 16.3 points. In other words, over this two year period, which reflects the inflationary influences of the Korean conflict, the medical

---

Director, Bureau of Medical Economic Research.

care index and the Consumers' Price Index have increased approximately the same number of index points. Durable consumer goods and food are particularly responsive to wartime uncertainties and, as they comprise a major portion of the Index, strongly influence the rapid increase (13.7 points) of the entire Index in 1951 and the much slower increase (4.1 points) in 1952 after the initial adjustments were completed. Medical care prices tended to rise more steadily over this period (7.1 points in 1951 and 9.2 points in 1952); these prices were, of course, less affected by the Korean situation.

The hospital portion of the medical care index registered by far the greatest increase of the medical care items. This increase of 28.1 points is considerably larger than the increase of 4.1 points in the Consumers' Price Index and the increase of 9.2 points in the portion of the index for medical care and drugs, of which it has been the most inflationary part. As we have previously stated, hospitals are buyers of large quantities of food and labor; they feel currently the full impact of inflationary forces. Since the base period, the increased costs of labor, food, and materials, combined with a shorter working day for nurses, are among the major factors forcing the upward adjustment in hospital room rates. It may be pointed out in passing that, while hospital room rates have increased, the average length of stay in the hospital has decreased so that the cost of hospital care for some illnesses is actually less than it was in 1935-1939. If the hospital items were excluded from medical care, however, the index for medical care would have been considerably lower than 164.2 in 1952.

TABLE 2.—*Effects of Shifting the Base Period from 1935-1939 to 1947-1949*

* These are published indexes; all other indexes in column were computed by the author from published quarterly indexes.
† December, 1950 = 100.

The index of hospital rates excludes the prices of laboratory and other services and is based on room rates only; the index of prescriptions and drugs does not include the new "wonder drugs." Realizing the necessity for adding such items, among many others, and for reflecting certain population changes, a thorough revision of this price index series was undertaken. Beginning in January, 1953, as a result of a comprehensive revision started by the Bureau of Labor Statistics in 1949, the Consumers' Price Index acquired a "new look." There is much evidence that consumers today are buying more and buying differently than they did in the 1930's. This revision was needed, therefore, to make the Index a more realistic measure of changes in consumers' prices in the 1950's.

SHIFTING THE BASE PERIOD

In addition to the revisions, a new base period, 1947-1949 = 100, replaced the old base period, 1935-1939 = 100, for each item as well as for the Index itself. The revisions could have been made without changing the base period. The purpose of table 2 is to show the effect of merely shifting the base. On the old base, the Consumers' Price Index for 1947, 1948, and 1949 was 159.6, 171.9, and 170.2; the average for these three years was 167.2. Setting this average equal to 100 obviously depresses the index points for 1950, 1951, and 1952 to about 60% (0.598, col. 2) of the levels on the old base. Consider the case for 1951 for which all the index numbers have been published. On the old base, the Index was 185.6, and, on the new base, it was only 111.0 (185.6 divided by 167.2 equals 1.110). How does this change in the base period affect the medical care portion of the Consumers' Price Index? On the old base, the medical care indexes for 1947, 1948, and 1949 were 131.6, 140.1, and 144.9—an average of 138.9, considerably lower than the 167.2 average for these three years for the entire Consumers' Price Index. Setting 138.9 equal to 100 depresses the values of the medical care items for 1950, 1951, and 1952 to about 72% (0.720, col. 2). The medical care portion of the Index stood at 155.0 in 1951 on the old base; this index becomes 111.1 (155.0 divided by 138.9 equals 1.116) on the new base. (The published figure is 111.1, not 111.6; the small difference could be due to rounding errors, changing weights, or the new influence of "group hospitalization.") In other words, both the medical care portion and the entire Consumers' Price Index were 11% higher in 1951 than in 1947-1949. It should also be noted in table 2 that shifting the base raises the index for physicians' fees in 1952 from being below the entire Index (152.2 and 189.7) to being practically on a par with it (113.2 and 113.5). This is even more noticeable for one of the five fees, obstetric case. Within the medical care field, the effects of base shifting vary greatly. Since the conversion factor for hospital rates, 0.487, is much smaller than for any other major subdivision of medical care and drugs, the index of hospital rates is depressed most by the shift to the new base period.

Shifting the base is a procedure that statisticians avoid in using published index numbers. In this case, the base shifting depresses the entire Index to 60% of the level on the old base and the medical care portion to only 72%. Now that the originator of the Index, the Bureau of Labor Statistics, has shifted the base (altered the weights and broadened the coverage), one is justified in pointing out that both the entire Index and the medical care portion thereof stood at 111 in 1951. In 1952, however, the medical care portion was 118.2 (estimated) as compared with only 113.5 for the entire Index; in 1950, also, the medical portion was higher, 106.0 and 102.8.

Medical care is not the only portion of the Index whose position relative to the entire Index was reversed by the shifting of the base period. Selected items are shown in table 3. The indexes for rent in 1947, 1948, and 1949 averaged 120.4. In 1951, the index for rent, 136.2, was considerably lower than the 185.6 of the entire Consumers' Price Index on the old base. Shifting to the new base period, 1947-1949, the index for rent becomes 113.1 (136.2 divided by 120.4 equals 1.131), which is higher than the 111.0 of the entire Index. Conversely, in 1947, 1948, and 1949, the indexes for women's cotton housedresses averaged 291.7. In 1951, the index for women's cotton housedresses was 282.5, considerably higher than the 185.6 of the entire Index on the old base. On the new base period, however, this item becomes 96.8 (282.5 divided by 291.7 equals 0.968), much less than the 111.0 of the entire Consumers' Price Index. Upon observing this figure, one might infer that the price of cotton housedresses is now below "par" and that they are very reasonably priced; most housewives would contend that cotton housedresses are not reasonably priced, no matter what the shift in base indicates. The index for personal care (services of barbers and beauticians and for cosmetics) behaves in much the same fashion. In 1947, 1948, and 1949, the indexes for this portion of the Index averaged 174.2. In 1951, the index for personal care was 192.5; this was also higher than the 185.6 of the entire Index on the old base. Shifted to the new base, this index becomes 110.5 (192.5 divided by 174.2 equals 1.105), lower than the 111.0 of the entire Consumers' Price Index on the 1947-1949 base. Again the effect of shifting the base is to suggest that the prices of personal care items were at very reasonable levels in 1951. Are haircuts now reasonably priced?

These three examples illustrate the effects of the shift of the base period on index items that rose rapidly in price during the early years (before 1950) of the present inflationary movement, particularly during World War II. The shift in the base period makes these items appear in a favorable light to consumers by the process of concealing the high levels that they had attained by 1947-1949. It is highly probable that, after a few years of seeing indexes on the new base period, the general reader will forget the high levels attained in the base period and there will be a new generation of shoppers. Although the public will be misled, experienced statisticians will not; they may, in attempting to avoid confusion, refuse to use the new base period and shift those revised indexes, which can be so shifted, back to the old preinflationary base period, 1935-1939. This temptation will be great for medical economists because there is general agreement that physicians' fees are among the relatively static prices in a broad inflationary movement, and 1947-1949 was a very disturbed period. Fee schedules are largely established through custom and tend to remain relatively static even when the price of a bushel of wheat and of a pair of shoes doubles. A fee does not increase from $3.00 to $3.10 to $3.20; it is more likely to stay at $3.00 until a jump to $4.00 or $5.00 is warranted. Hence the index of fees would jump in any quarter in which the fees were increased in a large number of the 34 (or 46) cities. The index of obstetric fees is currently the highest of the five fees (table 2). A major explanation is the exceedingly large number of births during the years after World War II. More generally, the factors responsible for boosting the indexes of medical care items came late and slowly in the long inflationary period starting around 1940. Because the old base period coincides with the start of the "wonder drug" era studded with many other revolutionary changes in therapy, it is preferred in the field of medical care. On the other hand, 1947-1949 is a poor base period because medical demobilization was taking place. About two-fifths of the physicians were in military service in 1945. Many of them did not return directly to practice or to their prewar home towns. Medical demobilization featured the last three years of the 1940's. From the standpoint of medical economics, those three years were far too disturbed to be chosen as a base or normal period. The general case against it is, of course, our main point.

AN ANALOGY

An analogy may be helpful to the reader in reviewing the very different effects that the shifting of the base will have on different portions or items in the Index. Shifting the base from 1935-1939 to 1947-1949 may be likened to two men climbing a hill. One man, with a head start, has climbed two-thirds of the way up the hill; his companion, who started later and climbed more slowly, has climbed only one-third of the way up the hill. Stopping on a shelf, the first man turns to his companion and says, "We will stop where we are and, even though I have climbed higher than you have, we will call your position or elevation from the foot of the hill 100% and mine 100%." When both men reach the top of the hill, therefore, the first (upper) man's position will be 150% while his companion's position will be 300%, even though both have climbed to the top of the same hill.

Never before in the long history of measuring changes in prices paid by consumers has the Bureau of Labor Statistics shifted to a later base period during the course of an inflationary trend. The original base period, 1913, certainly did not represent such a period; nor did the 1935-1939 base that followed it.[1] On the contrary, this latter period was representative of a postdepression or prewar era. From this period, the base has been shifted to a period of post-World War II inflation, with consumers having saved dollars to spend for goods of wartime scarcity. (The sharp increase in births might possibly be considered a postwar spending spree in the realm of medical care.) A brief examination of the Index for 1950, 1951, and 1952 shows that this inflationary period that started before World War II was not terminated in 1949, making the new base period an interim station in the inflationary trend; a shelf on a hillside. It is difficult, therefore, for one who has watched the development of this Index and used it frequently in his studies to accept this shift. Although the arguments for overhauling the Index are strong, it seems to us and to many other economists that it was a mistake to also select a new base period before the inflationary forces had run their course. Apparently the new base period was selected by the Bureau of the Budget, and the Bureau of Labor Statistics was requested to use it in order that all major index numbers published by the various Federal agencies would have the same new base period. The necessity for such uniformity is open to question.

TABLE 3.—*Comparisons of Selected Items on the Old Base and the New Base*

	1947-1949 Average	1950		1951	
Adjusted Indexes	Old Base (1)	Old Base (2)	New Base (3)	Old Base (4)	New Base (5)
Consumers' Price Index.........	167.2	171.9	102.8	185.6	111.0

	291.7	271.5	93.1	282.5	96.8

* Figures published by the Bureau of Labor Statistics; direct shifting of the base gives 106.5 in 1950 and 111.6 in 1951 for medical care.

OTHER CHANGES

There are other changes in addition to the shifting of the base period. Originally there were six major groups: food; apparel; rent; fuel, electricity, and refrigeration; house furnishings; and miscellaneous goods and services. In the revised index, rent, house furnishings, and fuel, electricity, and refrigeration are combined into one major group, housing. Medical care, personal care, transportation, and reading and recreation, which were formerly four subdivisions under miscellaneous goods and services, are now four major groups, bringing the total number of major groupings to eight. A slight revision in the medical care portion of the Index results from the addition of penicillin tablets, multiple vitamin concentrates, and other than nationally advertised aspirin to the drug and prescription items.

---

[1] The old base period is five years and the new base period is three years. Consequently, the old base period is somewhat broader. This advantage is difficult to evaluate; three years could be a sufficiently long time for a good base period. Furthermore, there has been criticism of the 1935-1939 base period on the grounds that the after-effects of the depression of the first half of the 1930's were much greater on some commodities and services than on others. Ideally, a base period should be a period of time in which the interrelationships of prices are relatively free from abnormal influences.

Many new items are priced in other sections of the Index, raising the total number of items priced from about 200 in the adjusted (old) index to over 300 in the revised index. Thirty food items have been added, as well as a considerable number of articles of clothing, house furnishings, and miscellaneous goods and services. Direct measures of the effect of price change on the costs of home ownership and home maintenance are obtained for the first time, in addition to direct pricing of restaurant meals, used cars, and other items not priced in the past.

Another change that has been incorporated into the revision deals with the importance of each of the items that goes into the revised index "market basket," i. e., the "weight" assigned to each item. In the unadjusted index, spending patterns of wage earners' and clerical workers' families for 1934-1936 were used as a base for weighting, while the adjusted index reflects buying habits for 1950 and the revised index reflects buying habits in 1952. Population weights used in combining the city indexes into a revised (national) index (and into the adjusted national index) are based on the 1950 census rather than on the 1940 census that was used in the unadjusted (national) index. The list of cities in which prices are sampled has been increased from 34 to 46 and is now representative of all urban places ranging in size from very large cities to towns of 2,500 population, rather than large cities only. All of these desirable revisions and extensions probably could have been made without shifting the base period.

The unadjusted index will be issued through June, 1953, to facilitate the transition to the revised index for users of the Consumers' Price Index. After that date, the reversals created by shifting the base period cannot be so easily demonstrated; they should not be forgotten. The breakdown on individual medical care items will probably not be available soon, as no exact date for the release of individual medical care items of the revised index has yet been set. When this information becomes available, a complete analysis of the data on medical care will be made as soon as possible by the Bureau of Medical Economic Research. Unless our present thinking changes, that analysis will involve shifting the indexes back to the old base period. Our critical attitude toward the new base period will not, however, conceal the evidence that many medical care items, including hospital room rates, have risen faster than the entire Consumers' Price Index since 1947-1949.

BUREAU OF LEGAL MEDICINE AND LEGISLATION

MEDICOLEGAL ABSTRACTS

Drunkenness: Admissibility in Evidence of Chemical Tests.—The defendant was convicted of causing death while operating an automobile under the influence of intoxicating liquor. From such conviction he appealed to the Supreme Court of Colorado.

After the accident, which gave rise to the prosecution, the defendant and the injured persons who were riding in the other automobile were removed to a hospital in Colorado Springs. A sample of the defendant's blood was taken, without objection, by a physician and thereafter analyzed by a registered medical technologist, with the result that it was found that the alcoholic content of his blood was "point two eight per cent. That is twenty-eight hundredths, or twenty-eight hundred milligrams per hundred cc.'s." The medical technologist further testified that "anything over one point five [sic] is considered under the influence of alcohol" and "would cause an impairment of his ability to drive." [Clearly what was meant was 0.15 not 1.5.] The highway patrolman who was at the scene of the accident and others who talked with the defendant after he was removed to the hospital, including the physician who attended him and took the sample of his blood, all testified that they detected the odor of liquor on his breath either at the time of the accident or shortly thereafter. The defendant contended that the admission of the testimony of the medical technologist was in error because of the following reasons: 1. It was incompetent. 2. It was violative of the defendant's constitutional rights and privileges.

The registered medical technologist, said the Supreme Court, was a college graduate and had had a year's special training at Toledo University, which is a school approved by the National Board of Registry. She had been employed at St. Francis' Hospital in Colorado Springs for about nine months, at Camp Carson near Colorado Springs for three and a half years, and at Memorial Hospital in Colorado Springs for a period of four and a half years, during all of which time she was engaged as a registered medical technologist, and her work involved blood and other analyses. She testified that in the analysis of the defendant's blood she used the Nicloux method, which is an accepted method of blood analysis. Her evidence was competent; its weight was for the jury's determination. There was testimony introduced on the defendant's behalf regarding the Nicloux method and its accuracy. Aside from any blood analysis, however, there was competent evidence sufficient to warrant the jury in determining that defendant, at the time of the accident, was driving under the influence of intoxicating liquor. Apart from the testimony of the registered medical technologist, the jury might properly have found the defendant guilty as charged. Neither we, nor the jury, the court continued, are sufficiently learned in the art of blood analysis to determine whether the Nicloux method or other of the methods to which defendant's physician testified is the better and more accurate method, but the weight to be given such testimony was a matter exclusively for the jury's determination, and we perceive no error in its reception.

Accordingly the conviction of the defendant was affirmed. *Kallnbach v. People, 242 P. (2d) 222 (Colorado, 1952).*

Taxes: Application of Social Security Taxes to Part-Time Industrial Physician.—This was an action by the Willard Battery Company to recover alleged overpayments of federal employment taxes on the salaries of part-time industrial physicians who examined and treated its employees. The case was heard in the United States district court for the northern district of Ohio, eastern division.

The contracts between the physicians and the plaintiff company, said the court, indicate that the rights and obligations of an employer-employee relationship were not being assumed. Professional services requiring a high degree of skill were contracted for, but direct control and supervision over the details and means by which the work was to be accomplished were not contemplated. The contracts provided that the physicians were to use such methods as they saw fit "in accordance with the best established practice." Under the contractual arrangements there was a mutual right to terminate. While the right to terminate might be construed to be a right of discharge (one of the indicia of an employer-employee relationship), such a construction of the provision here would not be realistic, because the parties were given the benefit of notice and there was no right to terminate immediately. The evidence shows that the physicians performed only part-time service for the plaintiff company. During the years in question, they maintained private practices, to which most of their time was devoted. They were free to leave the company premises even during the hours they were scheduled to work, if an emergency case in their private practice required their presence. The compensation they received from the company was only a fraction of their total incomes during the years in question.

One of the Treasury regulations as to who are employees provides: ". . . In general, if an individual is subject to the control or direction of another merely as to the result to be accomplished by the work and not as to the means and methods for accomplishing the result, he is an independent contractor. Generally, physicians, lawyers, dentists, veterinarians, contractors, subcontractors, public stenographers, auctioneers, and others *who follow an independent trade, business or profession,* in which they offer their services to the public, are independent contractors and not employees."

The court held that the plaintiff was entitled to a refund of the taxes it had paid. *Willard Storage Battery Co. v. Carey, Collector of Internal Revenue, 103 F. Supp. 7 (1952).*

Milk-Aspiration Pneumonia.—Autopsy studies on both infants and adults convinced Moran that pneumonia caused by aspiration of milk is commoner than most clinicians and pathologists realize. He found milk-aspiration pneumonia frequently in infants who had feeding problems due to prematurity, central nervous system defects, or obstruction of the esophagus. Aspiration of milk accounted for sudden death in one apparently healthy infant, 3 months old, who had been allowed to take his feeding mixture with his bottle propped against a pillow, without the mother's help. In adults this disease has been found most frequently in persons confined to bed, in elderly persons with impaired reflexes, and in mental patients. It may be found in association with pneumonias caused by liquid petrolatum or with the aspiration pneumonias produced by solid foods. It may result from direct aspiration of milk or from aspiration of vomitus containing milk. The pathological changes include acute pneumonia, abscess formation, focal and widespread granulomas, alveolar thickening, giant-cell reaction, and fibrosis. The reaction is usually mononuclear and granulomatous at the time of death. The author also studied the tissue reaction produced by intratracheal injection of varying amounts of feeding mixture, human milk, or cow's milk into rabbit lungs. A reaction to the milk occurred within a few minutes of the time of injection. Smears and sections of the bronchi showed numerous red blood cells, granulocytes, and macrophages. Occasional macrophages contained fat, apparently from the milk. Later reactions to injection of milk varied from acute pneumonia to focal and widespread granulomatous lesions with giant-cell reactions and fibrosis. Although some features of the disease both in human and in animal lungs resembled certain features of lipid pneumonia caused by liquid petrolatum or cod liver oil, the general reaction more closely resembled that seen in response to injection of solid foods. Because the response is to the milk protein as well as to the fat, the term milk-aspiration pneumonia more accurately describes this disease than terms such as lipid pneumonia caused by milk. Microscopic studies of the human and animal material suggest that many of the mononuclear pneumonias occurring in infants may be caused by aspiration of milk. The authors stress the need of instructing nursing personnel in feeding methods and general nursing care designed to eliminate the hazards of aspiration pneumonia.

Cortisone in Treatment of Bell's Palsy.—In 1951 Rothendler reported on a patient with Bell's palsy in whom cortisone proved effective. He now presents the histories of seven patients, in six of whom Bell's palsy was successfully counteracted with cortisone. The author feels that the ability of cortisone to relieve the acute edema and inflammatory reaction of the facial nerve and its sheath, which cause marked compression of the nerve as it passes through the bony portion of the fallopian aqueduct, explains the efficacy of cortisone in peripheral paralysis of the facial nerve. This makes possible early restoration of nerve function. After atrophy has taken taken place, cortisone cannot be expected to have a beneficial effect. It is assumed that this explains the failure of cortisone treatment in the seventh patient, in whom cortisone was given only after a severe paralysis had been present for 10 days, during which time nerve atrophy, as indicated by faradic test, had taken place. This does not imply that the nerve will be atrophied in all cases after 10 days, since the degree of atrophy also depends on the severity of the inflammation. It should be emphasized, however, that cortisone

Periodicals on file in the Library of the American Medical Association may be borrowed by members of the Association or its student organization and by individual subscribers, provided they reside in continental United States or Canada. Requests for periodicals should be addressed "Library, American Medical Association." Periodical files cover only the last 11 years, and no photoduplication services are available. No charge is made to members, but the fee for other borrowers is 15 cents in stamps for each item. Only three periodicals may be borrowed at one time, and they must not be kept longer than five days. Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted.

is not intended as a treatment of Bell's palsy of long standing. To produce the maximum effect promptly, large doses of cortisone were given initially. On the first day doses varied between 300 and 600 mg., being given in divided doses. In the first three cases the cortisone was injected intramuscularly, but the last four patients were given cortisone tablets by mouth.

Hexamethonium in Therapy of Hypertension.—A group of 58 unselected ambulatory patients with moderate to severe hypertension were given hexamethonium orally, and were followed for from 4 to 16 months. The dosage schedule must be individually adjusted for each patient, so that excessive hypotension and serious complications will be avoided. All but 11 of the 58 patients responded with a significant (more than 20 mm. Hg) decrease in blood pressure, and in about one-half of the patients the blood pressure in the upright position returned to normal. Patients with diastolic pressures above 140 mm. Hg required only slightly larger doses than did those with pressures between 100 and 120 mm. Hg. Patients with severe hypertension complicated by cardiac failure and renal disease seemed to be particularly resistant to therapy. Cerebrovascular disease and heart disease (cardiac failure and angina pectoris) seemed to be particularly benefited by a reduction in blood pressure with hexamethonium. Impaired renal function (even if uremia is present) is not a contraindication to hypotensive therapy. In the presence of renal damage, however, glomerular filtration is decreased and small changes may precipitate progressive renal failure; therefore in such cases reduction in blood pressure must be undertaken with extreme caution and with constant evaluation of renal excretory function. Any tendency toward an increase in blood urea nitrogen contraindicates further reduction in blood pressure. If close supervision and repeated evaluation of the blood urea nitrogen is not feasible, then therapy with hexamethonium is contraindicated. The administration of hydralazine (Apresoline) and hexamethonium in combination further improved the blood pressure regulation in 11 of 18 patients in whom adequate control was not obtained with hexamethonium alone. The authors conclude that hexamethonium chloride was superior to other orally active hypotensive agents used under similar circumstances.

Use of Curare in Electric Convulsive Therapy.—Although electric convulsive therapy has been proved effective for patients with depression, the depressive disorders of aged patients are often complicated by cardiovascular, neural, and skeletal disabilities, which make convulsive therapy hazardous. Patients with osteoporosis or osteomalacia have heretofore usually been denied electric convulsive therapy, because of the danger of compression fractures, but Gottlieb and Morris reasoned that these patients might be protected by curare. They report on six elderly depressed patients with severe osteoporosis of the spine and other physical disabilities who were treated by electric convulsive therapy after having been given curare. The method requires the administration of sufficient amounts of curare to produce paralysis of the voluntary musculature. Since this removes the patient's ability to breathe, it is necessary that respiration be adequately supported at all times; the technique should therefore never be undertaken by anyone who is not an expert in the maintenance of artificial respiration. In the patients described use of curare protected severely diseased vertebrae from further injury. Two of the six patients were completely relieved of their depression; two were partially relieved and were able to return home; in one patient, who had a focal cerebrovascular lesion, status epilepticus developed; and one died suddenly. All six aged patients were poor risks for any procedure; in addition to the depression and the severe osteoporosis of the spine, they also had cardiovascular and/or cerebrovascular disorders. Thus use of curare made electric convulsive therapy possible for patients who otherwise would have been unable to receive it. Edrophonium (Tensilon), which has been introduced as an antagonist of curare, was found not to provide sufficient anticurare effect to overcome respiratory paralysis. The authors feel that no antagonist of curare should be solely relied upon to overcome respiratory arrest, but should be considered as ancillary to administration of oxygen for maintenance of proper ventilation.

Exposure Treatment of Burns.—During the past three years over 300 patients with burns were treated by exposure to the air, with the patients placed in bed in the most comfortable position that completely exposed the affected areas. The successful application of this effective and practicable method of local care depends on the presence of hard crusts, formed chiefly from the exudate of partial thickness burns, and on the integrity of dry eschars composed of the dead skin of deep burns. The crusts and eschars serve as protection against infection; crusts desquamate when partial thickness burns are healed and eschars must be removed, preferably by excision, before full thickness burns are grafted. If fever, prolonged leukocytosis, suppuration, or any combination of these is taken as evidence of infection, 117 (77%) of the authors' 152 patients with partial thickness skin loss remained clinically free of infection at all times; minimal localized infection occurred in 26 patients (17%) and frank suppuration in only 9 (6%). As a result of their experience, the authors state that exposure to the air is indicated in all recent burns that can be completely exposed without undue difficulty or discomfort. Exposure is easily applied, but the configuration of some burns may pose problems. Circumferential burns of the trunk cannot be adequately exposed. The outstanding advantage of the method consists in the effective control of infection in most patients. Deep dermal burns heal uneventfully under crusts, which protect the burn from mechanical and bacterial trauma. The method is potentially dangerous in that it may encourage inexperienced personnel to delay skin grafting. If very deep dermal burns fail to heal in 21 days, the covering of such burns should be removed and skin grafting applied. Granulating surfaces must never be exposed. Judiciously applied exposure is as good as other methods and, in certain types of burns, it is definitely superior. In the initial care of a burn, exposure eliminates the need for elaborate aseptic technique and for expensive dressing; it is easily taught and can be rapidly accomplished. These advantages are particularly impressive in preparation for a disaster when facilities for the proper application of dressings would probably not be available. Like all other forms of therapy, exposure to air demands careful attention to the body's physiological requirements and to details of management. It is never an excuse for neglect.

Intestinal Anastomosis Without Clamps.—A simple, safe method of intestinal anastomosis has been devised by Berman and Mainella avoiding the use of cumbersome clamps that may cause trauma to the bowel. A foam rubber sponge is sterilized and cut to size on the operating room table to fit the circumference of the bowel in question. Usually 3 by 1 by ½ in. (7.5 by 2.5 by 1.3 cm.) is the size needed for small intestines. For large intestines a strip 4 in. long is necessary. In end-to-end anastomosis the technique used is as follows: Before the bowel is opened it is cleaned of its contents. The foam rubber strip is then wrapped tightly around the bowel and sutured through a bloodless area at the mesenteric border snugly enough to prevent escape of the bowel contents. The same procedure is performed at the opposite end of the segment of bowel that is to be resected. After the resection and anastomosis have been completed, the sutures are cut and the foam rubber removed. This method has been used likewise in lateral anastomosis, in ileostomy, and in resection of the large bowel, particularly the sigmoid. The new method is particularly useful in procedures affecting the small bowels, especially in children. There is no fear of leakage. It is also suggested for use in blood vessel surgery.

Serum Neuritis.—The occurrence of painful, long-lasting, and disabling neuritis as a complication of serum disease in 15 young men between the ages of 16 and 37 and one 65-year-old man is reported. Of the 16 patients, 15 had received tetanus antitoxin because of an injury, usually an occupational accident, while one patient had received antimeningococcus serum for meningitis. In all the patients the neuritis was confined to one or both upper extremities. In five patients the involvement was bilateral, but unilateral paralysis always occurred on the right regardless of the site of injection, with predilection for the muscles supplied by the fifth and sixth cervical roots. In the usual clinical course the onset of serum sickness occurs 3 to 10 days after the injection of foreign serum followed by signs and symptoms of neuritis from a few hours to a few days after the serum sickness. Two of the author's patients, however, had unusual clinical manifestations as follows: in one the neuritis occurred on the sixth day after the injection and preceded the serum sickness, since the characteristic urticarial rash appeared only on the 19th day after the injection; the other patient had generalized muscular fasciculations resembling clinically and electromyographically those observed in progressive muscular atrophy. Smooth muscle of the gastrointestinal tract was also involved, but all symptoms completely subsided within a week. In the author's series adequate follow-up was not secured; but in 14 patients in whom a reaction of degeneration was present, a significant degree of paralysis developed after three months in 5, and after six months in 8 patients, two of whom showed residual weakness of 12 to 18 months' duration. Only two patients had definite return to normal power which occurred within one and three months respectively; neither had electromyographic changes. Quantitative studies of electrical excitability have been found to be of prognostic value in determining the extent and duration of disability. The mechanism of production of serum neuritis has not yet been explained. It would seem important that, because of the industrial disability occasioned by the serum neuritis, the use of tetanus antitoxin, particularly in industrial practice, be avoided whenever possible by previous immunization with tetanus toxoid.

Routine Bone Marrow Culture for Histoplasma Capsulatum.—Rohn and Bond say that other investigators, on the basis of 193 tests with only one positive result, had concluded that routine cultures of the bone marrow for Histoplasma capsulatum have little value in histoplasmosis case-finding. Although their own observations on adults had likewise been largely negative, they decided to make routine tests for H. capsulatum on children, particularly since their Children's Hospital serves an area in which histoplasmosis is endemic. Of 76 bone marrow cultures in pediatric patients with a variety of hematological abnormalities, 5 (6.5%) yielded H. capsulatum. In two of the five cases of histoplasmosis, organisms were observed on direct examination of the marrow and cultures were only of confirmatory value. In the other three patients with histoplasmosis, direct examination of marrow showed no signs of histoplasmosis, but culture of the bone marrow yielded H. capsulatum and was the only means of establishing the diagnosis. In none of the cases in which bone marrow culture for H. capsulatum gave negative results could the diagnosis of histoplasmosis be established by other methods. The authors are of the opinion that, while routine marrow culture for H. capsulatum is of little value in adults, it is of considerable value for case-finding in infants and children.

Pelger-Huët Familial Anomaly of Leukocytes.—The anomaly of granulocytic leukocytes first described by Pelger in 1928 is characterized by a lack of normal segmentation of the nucleus. Although the nuclear chromatin is of the mature type, cells with more than two lobes to the nucleus are few and the majority of cells are unsegmented staff forms. Huët, in 1932, disclosed the hereditary nature of the anomaly. Yamasowa and associates describe the fourth case of Pelger-Huët anomaly observed in Japan. The patient was a 50-year-old woman. To obtain further information on the familial occurrence of this disorder, 74 of the 94 blood relatives in four generations and 5 of 25 living spouses were examined. Pelger's anomaly was found in 25 additional cases, that is, in a total of 26 out of 80. The studies confirmed the hematological findings described by Pelger and others, and the genetic data support Huët's concept of the simple Mendelian inheritance.

Potency of Corticotropin Preparations.—Rats whose hypophyses had been removed were injected subcutaneously or intravenously with two different types of preparations of corticotropin (ACTH); both preparations were obtained from frozen hog pituitary glands, but one from acid extracts and the other from basic or alkaline extracts of these glands. The left adrenal gland was removed one hour and the right adrenal two hours after the injections for determination of the ascorbic acid content. As much as 100 to 1,000 times as much corticotropin was required by the subcutaneous route as by the intravenous route to cause equivalent ascorbic acid depletion. Estimates of the relative potency of the two types of corticotropin preparations differed with the route of injection by 3 to 11 times. Different estimates of potency by the different routes of administration are important clinically because most corticotropin is used by routes of injection other than the intravenous route, which is used for standardization. Most differences in physiological efficacy of corticotropin are as readily explained on the basis of different rates of absorption, which depends on the route of injection and the nature and formulation of the preparation, as on the basis of a qualitative difference in corticotropin present, i. e., the multiple factor theory. The reported data are, therefore, interpreted as not supporting the multiple ACTH factor theory.

Treatment of Cervical Hostility Guided by Crystallization of Cervical Mucus.—Studies of the cervical mucus carried out by Campos da Paz demonstrated that a fern-like crystallization of the cervical mucus is present in the first half of the menstrual cycle and during the ovulation period. It is absent after ovulation, during pregnancy, and after the menopause, at which time only the cellular content of the mucus is evident. Only during anovulatory menstrual cycles with normal estrogen levels was fern-like crystallization of the cervical mucus observed at any time of the cycle. Fern-like crystallization is closely related to the estrogen function. Progesterone does not cause its appearance but on the contrary it seems to inhibit it. Fern-like crystallization is closely related to the receptivity of the cervical mucus to spermatozoa. As the crystallization loses its characteristic features, the receptivity of the mucus diminishes. When the crystallization is absent, the mucus as a rule is hostile to spermatozoa. These observations induced the author to give estrogens a therapeutic trial in 53 sterile women in the first phase of 215 menstrual cycles. All the patients treated had had negative results of a Simms-Huhner test during the ovulation period and absence of the fern-like crystallization of the cervical mucus. Estradiol benzoate was administered intramuscularly in all patients. The use of 5 mg. of the drug on the 10th day of the cycle in certain patients and on the 5th and 10th day in others were the schedules of treatment that gave the best results. With the fern-like crystallization test, the exact dose of estrogen to be used was determined easily in each case. Of the 53 patients treated by this method, pregnancy occurred in only 9. These apparently poor results are explained by the following facts: seventeen patients submitted to this treatment for one to three cycles only, abandoning it afterwards. In nine patients the inhibiting effect of cervical mucus was not the cause of the sterility. Eighteen patients are still under treatment. Of the nine patients in whom pregnancy was accomplished, fecundation occurred in the fourth cycle of treatment in two, in the fifth cycle of treatment in three, in the sixth cycle of treatment in two, and in the remaining two patients, in the eighth and tenth cycles of treatment. Estrogen therapy, although not definitely removing cervical hostility, is capable of producing the cervical receptivity necessary to the progression of spermatozoa into the cervix in every cycle. If the treatment does not give satisfactory results after at least six to eight cycles, the couple must be studied further for other causes of sterility.

Radiation Sterilization.—Tarpley and associates point out that one of the main advantages of sterilizing heat-sensitive pharmaceutical preparations with x-rays and gamma rays is the ability of these ionizing radiations to penetrate thick-walled packaging materials and yet cause a negligible temperature rise. Previous studies on the effect of radiation on various types of micro-organisms were carried out mostly with radioactive sources of low intensity. Sources of greater intensity (1,000 curie) and even more intense radioactive by-products from the atomic energy program are now available. Earlier investigations were carried out with 1.1 to 1.3 million electron volt gamma rays in the tubular radioactive cobalt (Co^{60}) and tantalum (Ta^{182}) sources developed by the Brookhaven National Laboratory. It was found that a very uniform radiation field exists within the central volume of these 1,000 curie sources which are contained in lead shields. The measurement of the radiation dose necessary to accomplish sterilization of a variety of micro-organisms and the effect on the sterilization dose of intensity of the radiation field were investigated. Heavily contaminated steroid suspensions were successfully sterilized by gamma rays produced by kilocurie sources of radioactive cobalt (Co^{60}) and tantalum (Ta^{182}). Radiation doses of between 2.7 and 3.2 megarep (rep $\times 10^6$) are required for sterilization when 0.1×10^9 organisms per milliliter are present initially. Clostridium sporogenes appears to be the most resistant organism studied in this investigation, molds and nonsporulating bacteria being killed more readily. A large fraction of the contaminating sporulating micro-organisms was destroyed by radiation doses of about 1.5 megarep, and those not killed showed morphological and cultural aberrations on subculture. Within the relatively long irradiation periods of this investigation, irradiation at lower intensity over long periods of time has no important bearing on the efficiency of the sterilization. This leads to the conclusion that many thicknesses of the material to be sterilized may be arranged around a radioactive source. By removing various portions at appropriate time intervals the radiation field may be utilized very efficiently.

Determination of Capillary Fragility by Means of Petechiometer.—In a previous investigation on 190 white male subjects Perry and Linden had found that the age of the subject and the time of the test exert some influence on the result of the Rumpel-Leede test. They now present the results of Petechiometer studies on 100 of these same persons. The Petechiometer consists of a bell suction cup 2 cm. in diameter. A cylinder containing a plunger is attached to the suction cup. The plunger has grooves, each of which represents an increment of 5 cm. Hg suction. With this apparatus suction ranging from 5 to 30 cm. Hg can be obtained. The various suctions are obtained by placing a stop ring on the appropriate slot on the plunger. The edge of the bell is lubricated with petrolatum and then firmly placed on the previously marked test site. Next the plunger is released, and the suction produced is applied for one minute. The lowest pressure yielding two or more petechiae was considered as the end point and was recorded as the capillary fragility (or resistance) of the test site. In each subject six areas were tested on contralateral sides. The results of the studies with the Petechiometer indicate that none of the six areas studied are adequate sites for measuring capillary resistance. The forearm, upper arm, and infraclavicular regions cannot be used because of the difference observed between the two sides. The back is not suitable because of its low median value. The thigh and legs might be of some value as test sites but require additional studies. Even if such studies would substantiate these regions for testing capillary resistance, many other factors are thought to exert some influence. The effects of temperature, barometric pressure, menses, thickness of skin, season, and allergies would have to be investigated before the Petechiometer could be considered as an accurate means of measuring capillary resistance in these areas. The authors feel that the Petechiometer is not a reliable instrument for measuring capillary fragility.

Studies with 8-Methoxypsoralen in Vitiligo.—Lerner and associates *report the results of clinical and experimental studies* with 8-methoxypsoralen (xanthotoxin, ammoidin). Of the nine patients with vitiligo treated with 8-methoxypsoralen, three patients showed striking improvement, two showed less but definite improvement, and four showed no change. The patients ranged in age from 15 months to 49 years and were treated for 1 to 20 months. The daily dose of the drug was 10 to 50 mg. given orally in divided doses supplied in 10 mg. capsules. Six of the patients showed no reaction to the drug, and three had mild symptoms not requiring discontinuation of the medication. It was observed that three of the nine patients dedeveloped marked increase in tolerance to ultraviolet light. It was not known whether this inhibition of the erythema reaction to sunlight was due to previous exposure to ultraviolet light or to the drug. *To study this problem further, 8-methoxypsoralen* was given to three persons with albinism. Two of the albinos were treated for three months and the third for two months. All showed decreased sensitivity to ultraviolet light. Two stated that they no longer wore hats when out in the sun. After discussing toxicity and in vitro studies with the drug, the authors say that the psoralen derivatives discussed in this paper have been isolated from a variety of natural sources, including expressed citrus peel oils, bergamot oil, and the plants, Ammi majus Linn, Angelica archanglica, and others. Whereas oral use of this drug decreases the erythema response of patients to ultraviolet light, local application increases this response. Persons handling the drug should not let it come in contact with the skin. One laboratory worker's arm came in contact with an alcoholic solution of 8-methoxypsoralen. Shortly thereafter, following exposure to ultraviolet light, a hyperpigmented spot developed on the arm. In appropriate doses 8-methoxypsoralen is well tolerated. Complete blood studies, urinalyses, examinations for urinary porphyrins, prothrombin times, and liver function tests, except cephalin cholesterol flocculation test, were within normal limits. Some patients had weakly positive cephalin cholesterol flocculation tests after two months of therapy. It is suggested that this test be done monthly for three months, and then at less frequent intervals, on patients receiving the drug.

Hearing Impairments in Children.—Of 2,628 cases in which the causes of hearing loss in children have been analyzed during the past 15 years, 1,688 (64.2%) were classified as cases of conduction loss and 940 (35.8%) as cases of perception loss. The ratio of conduction loss cases to perception loss cases thus was 2:1. Of the 940 children with perception loss, 310 had completely normal hearing in one ear with no hearing in the other ear; the remaining 630 had partial impairment in one or both ears. It has been calculated that in 1,155 (68.4%) of the 1,688 children with conduction loss, the loss was due to otitis media; it could have been prevented in nearly every case. There were 36 children with proved middle ear effusion; in these patients diagnosis has been made during the past four years, suggesting that middle ear effusion as a cause of hearing loss in children is on the increase. In 630 children with partial impairment of hearing in one or both ears, measles were found to be the possible cause in 109 and mumps in 22. While the incidence of measles is three times as great as the incidence of mumps, in this series measles appeared to be the cause of hearing impairment in five times as many cases as mumps. These findings suggest that the measles virus as a cause of perception hearing loss in children is probably of greater significance than has been reported in previous publications. Of the 630 children with partial perception loss, 461 had had more than one hearing test; 445 (96.5%) of these showed no appreciable change in their hearing, while 16 showed a progressive loss of hearing. This progressive loss was definite and extensive. Although the incidence of progressive perception hearing loss does not appear to be very great, when it occurs it is of serious consequence. The progress was not noted until a wearable hearing aid had been put on these children; in every instance the hearing loss was more pronounced in the ear in which the hearing aid was used. Sustained sound levels of high intensity can cause permanent cochlear damage in an otherwise normal ear, and this phenomenon may prevail in a previously damaged cochlea.

Ewing's Sarcoma.—Between 1930 and 1952 27 male and 23 female patients between the ages of 3½ and 43 years with histologically proved Ewing's sarcoma were treated at the Massachusetts General Hospital. Of the total, 36 were treated with external irradiation alone, 10 with radical surgery, and 4 by surgery followed by x-ray therapy. Thirty-three (66%) of the patients were less than 20 years old. In 34 of the 50 patients the location of the primary lesion was below the waistline. Only one of the surgically treated patients lived more than five years. Nine patients died of their disease, four within one year and five within 19 months to four years after operation. In this group the primary tumor was located, with one exception, in an extremity. Of the four patients in whom operation was followed by roentgen therapy, two, each with a lesion of a rib, died within six months; one with a tumor in a fibula died within three months, and one was lost to observation. Of the 22 patients who received external irradiation aimed at a cure of the disease, 4 survived without disease for 6½, 9, 12 and 13 years, respectively. Three others are living, one for four years but with disease, and two without disease for two years and six months respectively. Of the remaining 15 patients who died of their disease, 12 died within a year of treatment. Of 14 patients given palliative irradiation, 1 lived for seven years after the initial treatment and died of widespread metastases. Of the 22 patients treated by irradiation, 15 had no evidence of local recurrence of the tumor, the tumor was not controlled in 4, and the response to irradiation was undetermined in 3. The maximum tumor dose administered was 6,000 r. A dose as small as 1,000 r was sufficient to control the local lesion in one patient. It is believed that a tumor dose of approximately 4,000 to 5,000 r, fractionated at the rate of 200 to 300 r (air incident) per day, is probably sufficient for primary control of most Ewing's sarcomas. As a result of their experience, the authors consider external irradiation the method of choice in the treatment of this particular type of malignant tumor, which does not always follow the expected relentless course of a highly malignant neoplasm. External irradiation does not deprive the patient of a useful or cosmetically desirable part. In 4 (18%) of the 22 patients treated by radical irradiation, apparent cures were obtained. Palliative radiation therapy gave not only relief of discomfort but also an often unexpectedly long and useful life.

Dibenzyline in Treatment of Hypertension.—Dibenzyline (N-phenoxyisopropyl-N-benzyl-β-chlorethylamine), a specific, orally active, adrenergic blocking agent was given to 32 patients with severe essential hypertension. Outpatients were given one gelatin capsule of 20 mg. every five hours, and the dose was increased at weekly intervals until the blood pressure fell or toxic manifestations occurred. Hospitalized patients were given a 20 mg. increase in dose every four hours until a hypotensive effect or toxic manifestations occurred. Twenty-three patients (72%) responded with a fall of more than 20 mm. Hg in the mean blood pressure. In the standing position, the blood pressure decreased to less than 150/100 mm. Hg in 15 patients (47%). The average dose of the drug required by the responsive patients was 138 mg. four times a day in those with diastolic pressures over 140 mm. Hg, and 127 mg. four times in those with diastolic pressures under 140 mm. Hg. The largest dose used in the responsive patients was 360 mg. four times daily. A few patients required as little as 20 to 60 mg. four times daily. By the end of three months, administration of the drug had to be discontinued in 8 of the 23 patients who had obtained an initial hypotensive effect because of distressing side-effects such as tachycardia, dizziness, syncope, and gastrointestinal irritation. These side-effects could not be eliminated by variation in dosage even under hospital conditions. Only 11 of the 23 patients felt sufficiently benefited to continue the treatment for more than three months. These results were compared with those obtained in similar groups of patients, 54 treated with hexamethonium, 61 treated with extracts of Veratrum viride, and 52 treated with hydralazine (Apresoline). Comparison indicated that hexamethonium is the drug of choice in hypertension. Combined treatment with hydralazine was effective in about 50% of the patients who did not obtain an adequate reduction in blood pressure with hexamethonium alone.

Enteric Bacteria.—The hospitalization of an unusual number of patients with symptoms of gastroenteritis during winter and spring rather than in summer and fall when the incidence is usually higher, stimulated studies on the feces of such patients in an effort to identify causal agents. When it was found early in the course of these studies that Salmonella and Shigella organisms were not found regularly and it was apparent that most of the cases of gastroenteritis were not caused by such well-recognized pathogens, attention was directed to the identification of all types of bacteria isolated from the stools. In all, 571 cultures were performed with fecal specimens from 130 patients with gastroenteritis and 292 persons without gastrointestinal symptoms. Five patients with gastroenteritis harbored *different* types of Salmonella organisms, and four others harbored Shigella sonnei. Of the 130 patients with gastroenteritis (including the nine with Salmonella and Shigella species), 121 harbored strains of Paracolombactrum (paracolon) organisms, Pseudomonas aeruginosa, Alcaligenes faecalis, and four Proteus species. These types of enteric organisms were isolated from only 118 of the 292 patients who had no symptoms referable to the gastrointestinal tract. Eradication of paracolon and nonlactose-fermenting enteric bacteria from the intestinal tract resulted in apparent recovery in 44 more severely ill patients who were treated with chemotherapeutic and/or antibiotic agents. It is proposed that some Paracolobactrum (paracolon) strains and certain nonlactose-fermenting enteric bacteria deserve attention as possible causal agents of gastroenteritis, especially when adequate study fails to reveal well-recognized causal agents of gastrointestinal inflammation.

Portion of Parotid Duct Replaced by Plastic Tube.—Perkins and Ward present the case of a man, aged 46, who had accidentally shot himself in the left side of the face and head. The parotid gland could be seen deep in the wound, and 4 cm. of the parotid duct had been destroyed. A 6 cm. piece of polyethylene plastic tube was placed in the wound to bridge the defect and sutured to the proximal and distal ends of the parotid duct with 000 silk suture. No parotid secretions were noted draining from the wound either before or after secondary closure. The wound was treated with warm saline soaks, and the patient was given penicillin parenterally. Nine days after the operation a delayed primary closure of the face wound was done. The polyethylene tube remained patent, and there were no complications referable to the left parotid gland nine months following surgery.

Dextran for Nephrotic Edema.—A 10% salt-free solution of dextran was used in the treatment of the nephrotic edema of seven girls and five boys between the ages of 13 months and 14 years. The duration of the edema varied from one week to 16 months. All 12 children apparently had chronic nephritis; none had the so-called pure or lipoid nephrosis. Every child was hospitalized. Since a single infusion caused only a temporary increase in urinary output, to maintain the plasma colloidal osmotic pressure over a period long enough for removal of edema from the tissues, each child was given an intravenous infusion daily for 7 to 14 days. The dose of dextran was determined by the size of the child. Small children received 100 to 200 cc. of the solution, or 10 to 20 gm. daily. Large children were given 200 to 250 cc., or 20 to 25 gm. daily. The average daily dose was 1.43 gm. per kilogram of body weight. Treatment was discontinued when no further weight loss occurred or when it was obvious that diuresis would not take place. Seven of the 12 children had significant diuresis or loss of at least 15% body weight during and immediately after the period of treatment, but the diuretic effect was only temporary. All but one child had recurrence of edema after treatment was stopped. Three of the children showed reactions to the dextran during or after the first dose; the reaction was urticarial in two, and consisted in severe abdominal and back pain in one. No other deleterious effects were observed. Best results were obtained when dextran was given daily for 10 to 14 days. One child died 11 months after treatment, but information was not available regarding a postmortem examination.

Roentgen Hepatography by Injection of a Contrast Medium into Aorta.—Rigler and his associates found that the introduction of a somewhat modified technique for abdominal aortography made it possible to observe the hepatic arterial circulation. The technique differed from that previously used for abdominal aortography in the following respects: (1) 70% sodium acetrizoate (Urokon) was used as a contrast material; (2) 40 cc. was injected within three seconds by the use of a no. 16 needle and a veterinary syringe; (3) the needle was directed cephalad; (4) the needle was directed upward in such a way as to enter the aorta at the level of the 11th thoracic vertebra. A roentgenogram was made prior to the injection, and a second one immediately on its completion. A third roentgenogram was taken four seconds and a fourth roentgenogram eight seconds after the injection. The contrast medium extends into the kidneys and also passes into the lower extremities. Compression bags over the lower aorta and blood pressure cuffs around the legs increased the intensity of the liver shadow to a minor degree. The authors emphasize that the opacification of the liver is the result of venous return to the portal circulation from the mesenteric veins as well as of contrast material coming into the hepatic artery. In cases of cirrhosis of the liver the authors were able to show that the opacification is greatly reduced. In addition, they were able to demonstrate carcinomatous metastases in the liver as areas of diminished density. This was surprising, since in the case of kidney tumors, the introduction of contrast medium through abdominal aortography causes increased density within the neoplasm. It seems likely, however, that the lack of contrast in an area of metastasis, as well as throughout the liver in cirrhosis, is predicated on the compression of the sinusoids, which does not permit extension of the medium into the liver parenchyma as a whole and thereby reduces its opacification.

Percutaneous Transhepatic Portal Venography.—For the percutaneous transhepatic portal venography described by Steinbach and associates, the patient is placed in a supine position, inclined upward about 10 degrees. The epigastrium is prepared aseptically, and the tissues of the anterior abdominal wall just below the xiphoid process of the sternum are anesthetized. A 16 to 20-gage needle, 20 cm. long, is inserted through the abdominal wall. The needle is advanced through the liver until blood can be aspirated or until a depth of 15 cm. is reached, and the tributaries of the hepatic vein are entered. For venography 30 cc. of contrast medium are injected as rapidly as possible, and a roentgenogram is made immediately. This will demonstrate the intrahepatic portion of the portal vein and its branches. Percutaneous transhepatic portal venography has the following advantages over other methods of portal venography. 1. No major surgery is required. 2. The procedure can be performed in the radiographic room. 3. The intrahepatic vessels are more clearly demonstrated because the contrast material is injected directly into them. The disadvantages of the procedure are that only the intrahepatic portal venous system is demonstrated; that there has been some periportal extravasation of the contrast material with the present technique; and that a needle must be inserted through the liver parenchyma. Satisfactory venograms were made on two patients without liver disease, and in three of four patients with advanced portal cirrhosis. A venogram was obtained also in one case of metastases to the liver from a cancer of the ovary. Four venograms were unsatisfactory, one because of technical difficulties, two because the roentgen exposures were delayed until the contrast substance had passed through the liver, and the other as a result of injection of the opaque medium into the liver parenchyma. This patient experienced considerable pain. Further investigation is necessary before a final evaluation is possible.

Osseous Changes in Renal Insufficiency.—Generalized osteoporosis with or without metastatic soft-tissue calcifications, has been frequently described as a complication of chronic renal insufficiency. Davis now reports on a patient with chronic renal insufficiency who showed the opposite reaction, namely osteosclerosis. At autopsy this man, aged 68, showed chronic pyelonephritis with uremia; uremic pericarditis; diffuse osteosclerosis; congestive heart failure; old healed mitral and aortic valvulitis (rheumatic); generalized arteriosclerosis; and old syphilis. Osteosclerosis due to an osteoblastic reaction can occur in many different conditions. It has been shown in association with chronic renal insufficiency in rare instances and this entity is therefore to be added to the list of differential diagnostic possibilities when osteosclerotic changes are encountered. The present case radiographically simulated one of prostatic osseous metastases or atypical Paget's disease, but actually showed none of the classical findings of either. Postmortem examination excluded other causes for the osteosclerosis.

*Effect of Hyaluronidase on Experimental Exophthalmos. J. W. Nuzum Jr. —p. 550.

Transverse Incision in Pharyngeal Pulsion Diverticula.—Perzik believes that the transverse collar incision is the preferred approach in the surgical treatment of pharyngeal pulsion diverticula. It results in better exposure because of the improvement in the transverse diameter of the field, whereas the up-and-down extent is equal to that obtained with the vertical incision. The viscera of the neck can more easily be rotated in order to bring the neck of the sac into the open surgical field. In cases of miscalculation as to the side of presentation of the diverticulum, or in those rare cases of double bilateral diverticula, the collar incision can be readily extended to the other side, avoiding the making of a second vertical incision. As demonstrated in one of the cases reviewed here, lesions of the thyroid can be managed through the same incision. Finally, the cosmetic result of the collar incision is definitely superior to that of a vertical incision.

Effect of Hyaluronidase on Experimental Exophthalmos.—It has been demonstrated that exophthalmos follows increased secretion of thyroid-stimulating hormone by the pituitary. Nuzum made a series of studies to evaluate the role of water retention by the retrobulbar tissues in the pathogenesis of exophthalmos and to determine the effectiveness of hyaluronidase as a means of reversing the process. Hyaluronidase is an enzyme with the property of hydrolyzing hyaluronic acid, a mucopolysaccharide, which is a determinant of hydrophilic properties of the intercellular ground substance and the barrier role of the ground substance between cells. Increased amounts of hyaluronic acid have been demonstrated in the subcutaneous tissue in localized myxedema, and the clinical and pathological similarity of localized myxedema and exophthalmos has been recognized. Nuzum administered thyroid-stimulating hormone to intact guinea pigs and to guinea pigs from which the thyroid gland had been removed. He noted no gross difference in the degree or duration of exophthalmos in the two groups. He then injected varying amounts of hyaluronidase into the retrobulbar tissues and converted exophthalmos to enophthalmos in both groups. The duration of the enophthalmos induced was proportional to the amount of hyaluronidase injected. Enophthalmos induced in guinea pigs deprived of their thyroid developed more slowly even with higher doses of hyaluronidase than in the animals not subjected to thyroidectomy. Enophthalmos was not induced in a control guinea pig following the retrobulbar injection of hyaluronidase. The completely nontoxic character of hyaluronidase suggests its clinical trial in the management of clinical exophthalmos, although the transient effect detracts from its usefulness.

Excision of Sac and Aortic Suture in Saccular Aneurysms.—Saccular aortic aneurysms are usually caused by syphilis, and most of them occur in middle-aged patients, in whom they may be the only lesion threatening the patient's life and well-being. According to Bahnson, only two methods of treatment are currently in common use for aortic aneurysm, namely, intrasaccular wiring and the employment of fibrogenic or reinforcing materials. The former method, although beneficial to many patients, requires wire which, because of its special insulation, is no longer available. Wrapping with cellophane has given good results in isolated instances, but in a large series this technique has been helpful as palliation in only 40% of the patients. Although excision is an established method of treatment for aneurysms of peripheral arteries, it has been applied to aortic aneurysms only in isolated instances. Bahnson is convinced that excision of the sac and preservation of aortic continuity constitute the ideal treatment, since removal of the aneurysm relieves symptoms arising from pressure on nerves or vital structures and avoids later dissection or rupture. He presents the histories of eight patients who had saccular aneurysms in different regions of the aorta. In six excision of the sac and suture of the aorta were successfully carried out. The surgical technique is described, and drawings illustrate the various types of aneurysms observed in these patients and certain aspects of the operation such as the line of excision and the reconstruction after the excision. The author feels that resection of a saccular aneurysm with preservation of aortic continuity is feasible in all regions of the aorta. It is the procedure of choice in many instances.

Eosinophilic Granuloma of Vulva.—The histories of three patients with eosinophilic granuloma of the vulva are presented. After pointing out that reports of eosinophilic granuloma involving the vulva are rare, the authors show that there is evidence that eosinophilic granuloma of skin and bone, Hand-Schüller-Christian disease, and Letterer-Siwe disease are really different expressions of the same basic disease process. The same histological pattern is present in all except for certain occasional minor variations. Also, in general, each entity shows a tendency to involve certain specific tissues of the body, namely, bone, skin, lung, lymph nodes, spleen, and liver. This is probably an expression of the fact that it is a disease primarily involving the reticuloendothelial system. Numerous examples of cases depicting transitions from one of these entities into another can be found in the literature. The vulvar lesions are often symmetrical and tend to be eczematous and exudative in children but localized yellow brown tumors in adults. Eosinophilic granuloma is not confined to the younger age groups, and the disease process may be of many years' duration. When the disease produces localized swellings in the skin, these masses tend to localize around body orifices, i. e., the mouth, external auditory canal, perianal region, and vulva. The outcome in this disease is difficult to predict, but the disease tends to be shorter and oftener fatal in infants and children and of longer duration in adults. In the severe forms of the disease, treatment usually does not produce cure, but roentgen treatment or local excision may prove temporarily effective.

Urinary Excretion of Corticoids and 17-Ketosteroids Following Operations.—Hardy and associates determined urinary steroid excretion in patients before and after major operations. Excretion of corticoids was ascertained in four patients and of 17-ketosteroids in five patients and was correlated with certain aspects of nitrogen, creatinine, and electrolyte metabolism. Body temperature changes, total eosinophil counts, certain aspects of nutrition, and thyroid activity were also examined. The urinary excretion of corticoids increased in all four patients. The urinary excretion of 17-ketosteroids increased in three of five patients. There was a close inverse correlation between the total eosinophil count and the urinary excretion of corticoids following surgery. The eosinophil count decreased as the corticoid excretion increased. This consistent relationship was not observed between the total eosinophil count and the 17-ketosteroid excretion. In most patients, the postoperative increase in corticoid excretion is accompanied by an increase in the sweat potassium concentration and a decrease in the concentration of sodium and chloride. Following operation, the increases in the urinary excretion of corticoids, nitrogen, and creatinine showed similar time relationships. These increases were largely independent of changes in urinary volume.

Vesicourethropexy in Women with Urinary Stress.—Ward and associates say that before any treatment is instituted for the correction of urinary incontinence, the exact cause must be determined. A patient should be studied and treated with the groupings of Te Linde and Brack in mind: group 1, incontinence due to defects in the urinary system, congenital or acquired; group 2, incontinence due to neurological diseases; and group 3, stress incontinence. Stress incontinence occurs most frequently and has the greatest practical importance. The six women in this series all had exertional urinary incontinence. All but one had been delivered of full-term infants. The exertional urinary incontinence had been present from three to six years. None had had previous corrective gynecological procedures. Two of the patients had had pelvic musculature reeducation exercises for a period of three months each. The authors discuss the progress of these six women after their urinary incontinence was corrected by the suprapubic vesicourethral suspension operation of Marshall, Marchetti, and Krantz. The Marchetti modification of placing the sutures to exclude the catheter was used. The Foley catheter was removed immediately in two cases, and in 48 hours in four instances; however, in each instance there was hematuria for two days despite the fact that the sutures were placed to exclude the urethra. The indwelling catheter may cause some trauma in the vesical neck. Each of these women became continent immediately after the operation and remained so to date (3 to 19 months after operation). Before the operation two of the women had to wear vulvar pads because the slightest amount of exertion caused urine to gush from the urethra. The operative procedure is relatively easy.

Healing with Phemister's Method of Subperiosteal Bone Transplantation.—Ritter stresses the surprisingly favorable results obtained with Phemister's method of subperiosteal transplantation of a bone splint in the treatment of pseudarthroses and of slowly healing fractures of the long tubular bones. The fact that the healthy bone above and below the pseudarthrotic portion is only slightly separated from its periosteal trophic connection is regarded by Ritter as decisive evidence for the superiority of Phemister's over other methods. In this method the periosteum is lifted away from the bone only to permit the insertion of the piece of bone. For shaft fractures Phemister usually used bone splints from 7 to 12 cm. in length, and for those near a joint pieces measuring from 4 to 6 cm. Ritter's observations on the healing processes involved in the subperiosteal method of bone splint implantation were made on an extensive clinical material. His detailed descriptions are illustrated by roentgenograms, case histories, and diagrams. One diagram, which illustrates incorporation of Phemister's bone splint, shows marginal stretching of the periosteum and subperiosteal formation of osseous bars or clasps along the borders of the bone splint and the shaft of the bone; ossification of the pseudarthrosis takes place secondarily. Summarizing his observations, the author says that bone regeneration depends on functioning cells. Even though formation of new bone is possible through transformation of the nonspecific mesenchyma, in clinical use in human subjects a bone transplant covered with periosteum has proved superior. Phemister's method of subperiosteal implantation of a bone splint stimulates the growth potential of the healthy and eutrophic periosteum of the bone shaft. This method more than others takes advantage of the local biological conditions and requirements by early trophic attachment of the transplant, by immobilization of the old pseudarthrosis resulting from the formation of periosteal bridges between the transplant and the healthy bone shaft and by secondary ossification of the pseudarthrosis.

*Thorn's Reaction After Administration of Isoniazid. R. Marzo.—p. 137.

Thorn's Reaction After Administration of Isoniazid.—Thorn's reaction (decrease of eosinophils) was studied after administration of isoniazid to ascertain whether the drug, in addition to its antibiotic action on the tubercle bacilli, also exerts a stimulating action on the adrenal cortex. About 200 mg. of isoniazid were given to 10 healthy persons and to 10 persons with tuberculosis of various forms and duration who had never had the drug before. Thorn's test gave a negative result in all these persons. This phenomenon was ascribed to the amount of drug administered, which was not sufficient to produce an effective response of the adrenal cortex. Since it was believed that any larger quantity of the drug, even in divided doses, would cause side-effects, the same dose was given for six consecutive days to the same 20 persons and, in addition, to 10 healthy persons and 7 persons with tuberculosis. On the seventh day in all but three patients the number of eosinophils had dropped more than 40% and the urinary ratio between uric acid and creatinine had increased more than 50%. In one healthy person and one with tuberculosis the drop in the number of eosinophils was only 30%, but this might have been due either to some error of method or to a mild functional deficit of the adrenal gland. In the third person in whom there was no decrease in the number of eosinophils, tuberculosis was associated with diabetes mellitus. Thus, although the study was made in a relatively small number of persons, the author, in agreement with other workers, asserts that isoniazid does exert an effective "stress" effect on the cortex of the adrenal gland.

*Pathogenesis of So-Called Fever-Convulsions in Early Childhood. K. Betke and R. Gädeke.—p. 295.

*Aerosolization with Isoniazid as Method of Treatment for Pulmonary Tuberculosis. R. Wagner and H. Busse.—p. 300.

So-Called Fever Convulsions in Early Childhood.—The occurrence of abnormal reactions following smallpox vaccination is reported in seven children between the ages of 1 and 12 years. In three of the seven children a postvaccinal encephalitis was suggested by clinical symptoms, neurological findings, and changes in the cerebrospinal fluid. In three other children, a tentative diagnosis of "fever convulsions" was made because of the absence of abnormal neurological findings and changes in the cerebrospinal fluid and because the temperature was rapidly restored to normal. The seventh patient had intermittent clonic spasm of the extremities, the cerebrospinal fluid was normal, and temperature was gradually restored to normal within five days. Neither the prolonged fever nor the type of spasm was characteristic of fever convulsions, but proof of encephalitis was missing. In an additional 11-month-old patient in whom a clinical diagnosis of bronchopneumonia and meningoencephalitis had been made, necropsy revealed a pronounced cerebral edema with dilatation of vessels in the brain and meninges and dilated perivascular spaces partially filled with protein. In the authors' experience autopsy of young children with a clinical diagnosis of encephalitis reveals cerebral edema oftener than encephalitis. In white mice meningeal and cerebral hyperemia with exudation of plasma into the perivascular spaces resulted from single intramuscular or peritoneal injections of large doses of corticotropin (ACTH). As a result of their clinical and experimental experiences the authors consider an increase in the volume of the brain caused by hyperemia and edema to be the morphological substrate of the so-called fever convulsions in early childhood. The cause of these cerebral changes is the nonspecific, acute adaptation of the organism to an acute infection. The convulsions may depend on predisposing factors such as unfavorable environment, age (predominantly the second to the fourth year of life), or constitutional lability of vascular reactions. "Initial infectious convulsions" seems to be the correct term for these attacks. They are a symptom that does not offer any explanation with respect to pathogenesis and is of no value with respect to prognosis. On the basis of pathological findings, the authors have considered the possiblity that such convulsions are due to a permanent impairment resulting from destruction of ganglion cells.

Isoniazid Aerosolization for Pulmonary Tuberculosis.—Forty-nine patients with open pulmonary tuberculosis were treated with 25 or more inhalations of aerosol isoniazid. Of the 49 patients, 45 received one inhalation daily and 4 received two inhalations daily of 2.5 cc. of a 2% or 2 cc. of a 5% solution of a proprietary preparation of isoniazid (Neoteben) and of 2 cc. of an equivalent 2.5% solution of another proprietary preparation of isoniazid (Rimifon). The duration of the inhalation was about 15 minutes. The total number of inhalations varied from 25 to 98, with an average of 50. In all the patients previous treatment with *p*-aminosalicylic acid or amithiozone had failed. Eight of the 49 patients were considerably improved roentgenologically by the inhalation treatments and so were 21 who had received isoniazid both orally and by inhalation; 2 of the remaining patients were moderately improved, 17 were unchanged, and 1 became worse. The inhalations were very well tolerated. Nonspecific pharyngitis and laryngitis were not observed. Treatment had to be discontinued in three patients because of paresthesia in the extremities, tinnitus aurium, or increased serum bilirubin (2.56 mg. per 100 cc.). Better results were obtained with isoniazid aerosol therapy than with an aerosol preparation of water soluble thiosemicarbazone (Solvoteben). As a result of their experience, the authors recommend isoniazid aerosolization as an adjuvant in order to prevent increased resistance of Mycobacterium tuberculosis to isoniazid. Treatment with isoniazid orally and by inhalation alternating with amithiozone or *p*-aminosalicylic acid orally combined with thiosemicarbazone aerosol may be given a trial. Aerosol treatment should be given a trial not only in patients in whom exhaustive previous treatment with other drugs has failed but also in patients in whom stabilization could not be obtained by pneumothorax and in whom the bronchi are patent. Aerosolization does not seem to be promising with respect to the local effect in patients with residual cavities after plastic operations or if cavities are present in parts of the lungs to which the aerosol has no access as a result of the collapse.

Mercurialentis.—Hunter and Lister report on a case of mercurialentis (a colored reflex from the anterior capsule of the lens, believed to be due to a deposit of mercury) in a man, aged 58, who had been a thermometer maker for 35 years. In 1935 the bulb of a long pipe thermometer containing 2 oz (60 gm.) of mercury had burst in the man's hand, and some of the mercury had been deposited under the skin. Most of the mercury was removed at the time of the injury, but during the following week he developed ataxia and nystagmus. For two years his hand never healed completely. In 1937, a grey scarred mass was excised from the palm of the right hand. During the following two months, symptoms of mercury poisoning appeared, and he was never well from this time onward. Since 1947 he had complained of a staggering gait, of feeling unwell, and of continuous headache. Exposure to mercury ceased in March, 1948. When examined in 1951 he had vertigo, fine nystagmus, and paresis of the right external rectus muscle. On examination with the slitlamp, the lens showed a brownish, sharply defined anterior band. Examination with high power showed it to be very finely granular and to have an iridescent sheen. The authors cite several reports from the literature that indicate that mercurialentis is a common sign of prolonged exposure to mercury; it may be the only sign and once formed is permanent. Although the condition is usually of industrial origin, it can also be caused by prolonged use of yellow mercury ointment on the skin and even on the lid margins.

Oral Penicillin in Children.—A new penicillin salt, Penidural (N, N'-dibenzylethylenediamine penicillin) was given orally in doses of 300,000 units to 101 children, and the blood levels of the drug were determined three to four hours after its administration. Penidural was reliably absorbed in all patients irrespective of size and weight when a standard dose of 300,000 units was used. No attempt was made to work out a graded system of dosage according to body weight, but it is possible that in the smaller children therapeutic blood levels might be obtained with smaller amounts. In acute infections blood levels obtained during the first six hours with oral administration alone cannot be regarded as adequate, and two patients with osteomyelitis and three with pneumonia who were given Penidural were also given a single intramuscular injection of a large amount of crystalline penicillin to augment the blood level during this period. In these patients the results obtained were as good as would have been expected with intramuscular administration of penicillin. A rational scheme of treatment of acute infection appears to be an initial intramuscular injection of 600,000 units of Penidural and 100,000 units of crystalline penicillin, with 300,000 units of Penidural orally, the treatment continuing thereafter only with Penidural orally. Such a scheme will produce reliable therapeutic penicillin levels and should be adequate to treat infections due to penicillin-sensitive organisms.

Transfusion Reactions.—Incompatible reactions after transfusion of group O Rh-negative blood in a 26-year-old woman and in a 42-year-old woman are reported. The first patient received the transfusion because of hemorrhage during cesarean section for delivery of her third infant; the transfused Rh-negative cells had undergone hemolysis, resulting in a severe chill followed by jaundice and oliguria for 48 hours. Laboratory investigation showed the patient's blood to be group

O Rh-positive, Rh genotype cDE/cDE; immune antibodies, type anti-e + anti-C were demonstrable in the patient's serum to a titer of 256 with homozygous e-positive red cells (Rh-negative cells, cde/cde) suspended in sodium chloride solution and in albumin. The titer against heterozygous cells (R_1R_2, CDe/cDE) was 64. The second patient received repeated blood transfusions for menorrhagia; one transfusion of group O Rh-negative blood was not followed by serious reaction, but a second transfusion nine days later caused a chill followed by jaundice, hemoglobinuria, and oliguria for the next seven days. Serological investigation demonstrated the patient's blood to be group O Rh-positive, Rh genotype CDe-CDe. Immune antibodies of the type anti-c + anti-E were demonstrable in the post-transfusion sample of her blood to a titer of 32 in sodium chloride solution and 256 in albumin against homozygous c-positive cells (Rh-negative cells, cde/cde), and 2 to 4 in sodium chloride solution and 16 to 32 in albumin against heterozygous c-positive cells (R_1r, CDe/cde). The patient's post-transfusion blood sample contained no Rh-negative cells, thus confirming that the blood transfused was incompatible. These two cases illustrate the particular risk that recipients of blood transfusions incur if they are Rh-positive, since the immune antibodies they have developed may well be of the type anti-c or anti-e, and thus active against Rh-negative corpuscles (cde/cde). In some instances incompatability from antibodies can be detected in vitro only by complicated methods of direct matching, such as an indirect antiglobulin technique or a titration procedure using bovine albumin. In neither of the author's two patients, although their histories indicated the need, had such serologic investigations been made before the transfusion accidents. The case of the second patient further illustrates that, although a patient may be transfused without serious reaction with blood of a certain ABO and Rh group, this does not mean that a later transfusion of blood of the same ABO and Rh group will be similarly unaccompanied by incompatible reaction. It is important to bear in mind that the transfusion of blood can result in formation of dangerous antibodies, and any further blood for transfusion should invariably be matched on a freshly taken sample of the recipient's serum if more than 48 hours have elapsed since a previous transfusion.

*Postoperative Study of Thrombocytes with Reference to Thromboembolic Complications. P. Serra and A. Parma.—p. 124.

Postoperative Study of Thrombocytes.—A postoperative study was made of the thrombocytes of 106 patients who, because of age and/or the type of disease that had justified the intervention, had a tendency to thromboembolic complications. The preoperative count had revealed an average of from 300,000 to 350,000 thrombocytes per cubic millimeter, varying according to the patient's disease and general condition. The first postoperative count was made 24 hours after the intervention with the patient fasting, and the others were taken every 24 to 48 hours thereafter. Seventy-six patients had an uneventful postoperative course, and 59 of them (77%) had thrombocytosis. This, as a rule, became evident 24 to 48 hours after the intervention and usually lasted less than four days. Its initial phase and duration were not correlated with the patient's disease and the type of operation. Nine of these 76 patients were not considered because they had an increase of less than 50,000 thrombocytes. In the other eight patients the number of thrombocytes remained unchanged or decreased slightly, but these findings were ascribed to some mechanical error in the method used. A pronounced thrombocytosis (two to three times greater than the preoperative values) was found in nine patients whose postoperative course was complicated by infection. When the patient began to recover, the number of thrombocytes simultaneously began to return to normal. The postoperative course of 19 patients was complicated by phlebothrombosis of the deep veins of the leg, severe thrombophlebitis, and pulmonary embolism. All but one of these revealed a thrombocytopenia that had appeared before or at the onset of the clinical signs of the thrombotic process. This thrombocytopenia occurred in various ways and lasted several days. The number of thrombocytes began to increase when the patient began to recover either spontaneously or with ethyl biscoumacetate (Tromexan) and heparin therapy. In two patients whose postoperative course was complicated by infection and thrombosis concurrently there was no change in the number of thrombocytes. This suggests that the effect of the two entities on the thrombocytes superimposed and annulled each other. Since a more or less pronounced thrombocytopenia was a constant phenomenon in patients whose postoperative course was complicated by a thromboembolic process, a postoperative study of the patient's thrombocytes may be a valuable adjuvant in the early diagnosis of these complications. It may prove especially valuable when these processes develop in areas that are clinically difficult to explore, such as the pelvic and femoral vessels and the chambers of the heart.

Anemia Associated with Diaphragmatic Hernia.—The occurrence of hypochromic anemia in two women, aged 50 and 61 years, with diaphragmatic hernia is reported. In the younger patient the anemia was mild and occult blood was demonstrated in the feces; the older patient had severe anemia (with a hemoglobin level 26% of normal) and large amounts of blood were found in the feces. In the first patient the diaphragmatic hernia was acquired, there was no hernial sac, and the condition probably was due to a sudden increase of the internal abdominal pressure. The second patient had a hiatus hernia of type 2 according to Akerlund's classification, with a shortened esophagus that opened into the epiphrenic sac of the stomach. On surgical intervention in both patients an ulcer was detected in the cardial portion of the stomach at the level of the hernial aperture; it had not been demonstrated roentgenologically before the operation. This ulcer was the cause of the anemia. Pathogenesis, symptomatology, and diagnosis are briefly discussed. The severe anemia in the older patient improved considerably following preoperative treatment with large doses of iron and blood transfusions. Surgical treatment by the transthoracic approach was successfully carried out in both patients and should be practiced in all cases of diaphragmatic hernia associated with anemia, provided there are no clear contraindications. Because it restores anatomic conditions, it is the method of choice in traumatic diaphragmatic hernia. Phrenicotomy with or without thoracotomy may be performed for hiatus hernia with shortened esophagus; the dilated hiatus of the diaphragm may be narrowed by suturing the diaphragm to the prevertebral fascia and fixing the edges of the narrowed hiatus at the stomach at the level of the cardia. Because of the frequent association of anemia with diaphragmatic hernia, the presence of the latter always should be considered in cases of anemia of uncertain origin.

*Intra-Arterial Therapy of Endarteritis Obliterans. R. Marinoni.—p. 77.

Intra-Arterial Injection of Antazoline in Endarteritis Obliterans.—Ten patients with thromboangiitis obliterans of varying duration were treated with intra-arterial injections of 0.1 gm. of antazoline (Antistine) hydrochloride combined with 10 cc. of a 1% procaine hydrochloride solution. The injection was given slowly in Scarpa's triangle and immediately thereafter a band was tied around the thigh for five minutes. A total of from 3 to 12 injections proved sufficient to bring about an improvement in all but one patient. In this patient, a 43-year-old man, thromboangiitis was associated with lesions secondary to frostbite, and after seven injections his condition was still unchanged. All the other patients reported a marked diminution of nocturnal pains, a 9 to 10 times greater walking endurance before onset of pains in the extremities, a diffuse sensation of warmth in the entire leg with profuse sweating of the foot for from one-half to two hours after the injection, and at the time of the injection an unpleasant, warm, burning sensation radiating to the great toe. This sensation was not felt by the patient in whom the therapy failed. There was never any side-effect, and only three patients were hospitalized for the treatment. The improvement is still present in all the nine patients 40 days to 8 months after the end of the treatment. Although the author cannot as yet explain the mechanism of action of antazoline in these patients, he suggests that the presence of the histamine-antagonizing agent in an optimum concentration in the altered vascular tissue is effective in inactivating the histamine produced by the tissue and bringing about, even if only temporarily, a balance.

Femoral Nerve Lesion in Hemophilia.—Certain complications of hemophilia, such as hemarthrosis, occur so frequently that absence of hemarthrosis in a hemophilic patient surviving into adult life casts doubt on the diagnosis. Involvement of the nervous system, however, is rare, as is proved by a review of the literature. Lyons describes a youth, aged 19, who had been hospitalized on many occasions for bleeding episodes. One maternal uncle died of hemorrhage when 12 years old. Another was "subject to bleeding." His brother was a bleeder from birth and died from hemorrhage at the age of 3 years. The youth's complaint was of pain in the left hip, and pain and swelling in the left groin. He also complained of tingling and numbness on the lateral side of the left thigh. His left hip was held in flexion and a large hard mass was palpable just above the inguinal ligament. He was unable to extend his left knee, and the quadriceps muscles were flaccid and wasted. The left knee jerk was absent. There was extensive sensory loss for pin prick and light touch in the area supplied by the femoral nerve and the lateral cutaneous nerve of the thigh. Aspiration of the hematoma deep in the psoas muscle was done a month later, because its size had shown no change. The pain in the iliac fossa was somewhat relieved after this, but no change was noticeable in the function of the involved nerves until about 7 months later. Then a transient disturbance in the radial nerve developed. In quoting from a summary report on nerve lesions in hemophilia, the author says that the femoral nerve was affected in 7 of 11 patients with involvement of the peripheral nerves. Diagnosis should present no difficulty provided the possibility of a peripheral nerve lesion is considered; however, on account of psoas spasm and pain referred to the hip joint, it may be mistaken for hemarthrosis in this joint. Further examination will reveal the inability to extend the knee, the loss of the knee-jerk, and extensive sensory loss. A mass is always present in the iliac fossa, pointing to the cause of the paralysis, a large hematoma in the psoas muscle. The prognosis is on the whole good, with the majority of patients recovering completely.

Glomerular Filtration and Renal Blood Flow in Toxemia of Pregnancy.—According to Bucht and Werkö, the kidney has been thought to play an important part in the development of toxemia of pregnancy, but a change in renal function pathognomonic for toxemia of pregnancy has not been demonstrated. Several investigators using clearance techniques studied the changes in renal function during toxemia. The studies reported here also concerned the clearance techniques and compare the values found in normal pregnancy with those found during toxemia of pregnancy. The renal clearance of inulin and *p*-aminohippuric acid was studied in 28 cases of toxemia of pregnancy. In all cases the study was repeated once or twice after termination of pregnancy, up to two years after delivery. The authors found that inulin clearance is the best measure of the glomerular filtration rate and the *p*-aminohippuric acid clearance of the renal plasma flow in toxemia of pregnancy. Inulin clearance is lower than normal in toxemia of pregnancy, but it undergoes a rapid increase after delivery. This speaks against organic changes as a cause of decreased filtration rate. Other possible causes are discussed. The *p*-aminohippuric acid clearance is also lower than normal in toxemia of pregnancy. The *p*-aminohippuric acid clearance does not increase to normal immediately after delivery but increases slowly and in some cases not at all. In the latter cases arterial hypertension does not necessarily develop within the time of observation (two years). The filtration fraction did not show typical changes in toxemia of pregnancy. There was no correlation between the extent of renal changes and the death of the fetus.

Influence of Vitamin B_{12} or Levulose Content of Blood.—Steinitz reported in 1937 that the increased blood levulose concentration that results from the administration of levulose can be reduced by administration of liver extract. Stuhlfauth noted that the same effect could be obtained when, instead of liver extract, he administered from 15 to 30 μg of vitamin B_{12} intramuscularly after levulose had been given either intravenously or by intraduodenal drip. Stuhlfauth was interested in ascertaining whether this reduction in the blood levulose content, which he had obtained in 30 subjects, including some with hepatic disorders and with obesity, would also influence other constituents of the carbohydrate metabolism. For this purpose levulose was introduced into the duodenum of 10 fasting persons. When 1 liter of 5% levulose solution was given hourly, the blood levulose concentration was found to be between 30 and 50 mg. per 100 cc. after about 120 minutes and remained at this level when the levulose administration was continued at the same rate. The dextrose content, however, was found to decrease by from 10 to 20 mg. per 100 cc. The lactic acid did not noticeably increase with this relatively slow administration of levulose. The pyroracemic acid was usually only slightly increased (0.5 mg. per 100 cc.), and the inorganic phosphate decreased slightly (2 mg. per 100 cc.). If, after the levulose content has reached its maximum, that is, two hours after onset of infusion, the patient is given 30 μg of vitamin B_{12}, the levulose nearly always decreases by from 10 to 25 mg. per 100 cc. The blood dextrose then increases slightly, without reaching the former level. Lactic acid usually increases noticeably, sometimes to twice its original value, one hour after injection of vitamin B_{12}. The pyroracemic acid decreases following a slight temporary increase. The inorganic phosphate one hour following the injection of vitamin B_{12} shows a renewed increase, which is followed by a temporary decrease. The reduction in the blood levulose content occurs only after injection of vitamin B_{12} or of liver extracts. Cobalt, folic acid, and adrenal cortex extract did not have this effect on the levulose content of the blood. Administration of 30 μg of vitamin B_{12} to eight fasting healthy persons who had not been given levulose likewise showed a slight decrease in the general function of reduction. In five patients with diabetes no uniform changes could be observed. The author concludes that the changes appearing simultaneously in the serum contents of dextrose, pyroracemic acid, and inorganic phosphate indicate that vitamin B_{12} induces increased utilization of levulose.

Licorice and Cortisone in Addison's and Simmonds' Disease.—Some of the adrenal cortical hormones influence the renal function in that they promote retention of sodium, chloride, and water but cause greater excretion of potassium. When administration of these hormones is stopped, there is a "rebound"; potassium is retained and extracellular fluid is excreted in excess. Desoxycorticosterone possesses this property to a greater degree than the glycocorticoids, cortisone and hydrocortisone. It was demonstrated in 1950 that oral administration of extract of licorice or of the glycyrrhizinic acid obtained from it, has the same effect as administration of desoxycorticosterone. Borst and associates of Amsterdam discuss the response to licorice in patients with Addison's disease and in Simmonds'-Sheehan disease, citing case histories. They found that the desoxycorticosterone-like effect of licorice, which is always seen in persons with intact suprarenal glands, was absent in three patients with Addison's disease. One of the three had suffered from suprarenal insufficiency for only a short time and had at first reacted well to licorice. In these three patients administration of 2.5 mg. of cortisone daily, divided into eight doses, partially restored the effect of licorice on the mineral metabolism. A dose of 10 mg. of cortisone restored the effect fully. A patient with Simmonds'-Sheehan disease reacted favorably to licorice. A good response followed treatment either with licorice and cortisone or with licorice and corticotropin. Two of the patients with Addison's disease who were treated with licorice and corticotropin simultaneously failed to respond. It is probable that patients with Addison's disease who respond favorably to licorice still have remnants of functioning suprarenal tissue, but there is as yet no direct evidence of this. The authors say that their observations throw no light on why the effect of licorice in normal subjects varies so much. The intensity of the response is not determined by the amount of glycocorticoids produced by the suprarenal glands unless this falls below a certain level. At the moment the most attractive hypothesis is that the "weak reaction" of certain subjects is merely the consequence of a very active counteracting homeostatic mechanism.

Effects of Licorice on Salt and Water Metabolism.—Following reports that in one case Addison's disease was controlled with licorice and in another case with salts of glycyrrhizinic acid, a component of licorice, Card and associates investigated these effects and examined certain components of licorice for desoxycorticosterone-like activity. They found that block juice, a preparation of crude licorice, is capable of producing water, sodium, and chloride retention in normal persons. Glycyrrhetinic acid, which occurs in licorice in the form of its glucuronide (glycyrrhizinic acid), reproduced the effects of crude licorice in normal subjects. Glycyrrhetinic acid, when given to one patient with Addison's disease, had effects on weight and electrolytes similar to those found after the administration of desoxycorticosterone and cortisone. In contrast to desoxycorticosterone, crude licorice and glycyrrhetinic acid did not prolong the survival of rats whose adrenals had been removed.

Treatment of Tetanus.—In past decades the treatment of tetanus was often disappointing, because even heroic doses of antitoxin may be without value once the toxin is fixed in central nervous tissue and florid symptoms have developed. This paper reports observations on six patients with tetanus, four of whom recovered. The authors are convinced that in all but the mildest cases treatment of tetanus should consist of an integrated therapeutic attack designed to keep the patient alive while the effects of the toxin wear off. The neutralization of toxin, suppression of exhausting spasms, the prevention of bronchopneumonia, and the maintenance of an optimal state of nutrition are of vital importance. The following measures should be adopted: 1. At least 250,000 units of antitoxin should be given on the patient's admission to hospital, half of this by the intravenous route. 2. Early tracheotomy should be performed as a routine measure. 3. Every six hours 500,000 units of penicillin and 0.5 gm. of streptomycin should be given. 4. If a wound is present, early wide excision should be carried out. 5. Continuous intragastric feeding should be instituted. 6. Continuous administration of gallamine (Flaxedil) triethiodide should be carried out by intravenous drip. 7. Minimal sedation with short-acting barbiturates, such as thiopental (Pentothal), should be used. In severer cases it may be necessary to keep the tracheotomy tube in place for two or more weeks and to continue with the intravenous use of gallamine triethiodide for a similar period.

Effect of Probenecid on Penicillin Content of Serum After Oral Administration.—Frisk and his associates report that the simultaneous administration of probenecid and penicillin noticeably increases the serum concentration of penicillin compared with the concentration reached by corresponding amounts of penicillin alone. With dosage of from 0.25 to 1 gm. of probenecid there is a linear relationship between the amount of probenecid given and the serum penicillin level attained. With the aid of probenecid, oral penicillin therapy can be carried out with smaller penicillin doses given at longer intervals. A dosage scheme of 500,000 units penicillin together with 1 gm. of probenecid every eight hours gives a minimum penicillin level in the serum of 0.1 unit per milliliter. The toxicty of probenecid is low and the substance is well tolerated. The present method of administering penicillin will probably largely be replaced by oral penicilln-probenecid therapy. An oral dose of 500,000 units penicillin with 1 gm. of probenecid every twelve hours may be considered sufficient for the treatment of most infectious diseases due to penicillin-sensitive bacteria. The combination of penicillin and probenecid in one tablet simplifies administration and does not affect the resorption of the substances. Probenecid will also be valuable in the treatment of infections that respond only to massive penicillin therapy; the authors' experiences in treatment of subacute bacterial endocarditis show the effectiveness of the combination of massive intramuscular doses of penicillin and probenecid.

Use of Succinylcholine Iodide in Electroshock Therapy.—Experimental and clinical studies were carried out to determine a practical standard dose of the muscle relaxant, succinylcholine iodide, for use in electroshock treatment. Electromyographic recording of the convulsions after different doses of this agent showed 0.25 mg. per kilogram of body weight to be suitable for men and 0.15 mg. per kilogram for women. Succinylcholine iodide was combined with 0.15 gm. or in exceptional cases with 0.20 gm. of Evipan (N-methylcyclohexenyl-methyl barbituric acid) and injected intravenously over a period of one minute while oxygen was insufflated. The electroshock was given about 20 seconds after the end of the injection. Clinical tests in 74 patients, 32 men and 42 women, in 339 electroshock treatments showed noticeable reduction of the severity of the convulsions in almost all cases. Few skeletal and no other unfavorable reactions occurred. The postconvulsive apnea rarely lasted longer than 30 seconds and never longer than a minute and a half. The only measure necessary in these cases was insufflation with oxygen for at the most one minute. Patients who have fragile bones or are otherwise feeble may require larger doses. If considerably larger doses of succinylcholine iodide are given, the simpler anesthesiologic methods of keeping the air passages open must be mastered. Holmberg and his co-workers conclude that because of variations in individual sensitivity to the muscle-relaxing substance and in skeletal and muscular strength no generally applicable standard dose can be set that will in all cases protect against injury and never cause respiratory arrest, but by individualization and adjustment of the dose the aim can be more nearly realized. During the last six months about 1,000 treatments were given along the lines indicated, without skeletal, respiratory, or other complications.

*Blood Withdrawal by Catheterization of Right Heart in Treatment of Acute Pulmonary Edema. L. Provenzale.—p. 304.
Syndrome Produced by Use of Electroshock with Electronarcoshock Therapy. P. Paladini.—p. 313.

Blood Withdrawal From Heart of Patients with Pulmonary Edema.—Provenzale reports on four patients with secondary pulmonary edema in whom, all treatments having failed, he removed blood from the heart by means of a catheter introduced into the right atrium. The first patient was a 64-year-old man in whom severe pulmonary edema followed pneumonectomy for carcinoma of the right lung. The removal of about 350 cc. of blood from the cubital vein and administration of morphine and other drugs were unsuccessful. His general and local condition improved greatly, however, when a catheter was placed into the right atrium through the basilic vein and 375 cc. of blood were withdrawn slowly. The second patient was a 51-year-old man in whom edema developed after pneumonectomy for neoplasm of the left lung. On the seventh postoperative day, all treatment having failed to relieve the edema, a catheter was introduced into the right atrium. The pressure was 20/6 mm. Hg in the atrium, 80/18 mm. Hg in the right ventricle, and 80/22 mm. Hg in the pulmonary artery. The values before pneumonectomy were 11/2, 40/5, and 40/16 mm. Hg, respectively. About 330 cc. of blood were removed, and the patient's condition was much improved. One month later the pressures within the heart and the pulmonary artery were normal. In both patients the improvement began after about from 100 to 150 cc. of blood had been removed. When, without removal of the catheter, the withdrawing process was stopped at this point, dyspnea and edema reappeared within a few minutes. In the other two patients edema was secondary to lesions of the mitral valve. This procedure failed in one of them because it was used in extremis. In the other it caused regression of the edema, but the patient died 11 days later of a cerebral embolism. To better ascertain the mechanism of action of this method, the author made experiments on three groups of rabbits. All of them were given an intravenous injection of 1 mg. of epinephrine per kilogram of body weight to produce pulmonary edema. Then 30 to 35 cc. of blood were withdrawn from a peripheral vein of the animals of the first group. All of them died from the pulmonary edema, which was confirmed at autopsy. When from 30 to 50 cc. of blood were removed from the right side of the heart of the animals of the second group, only 50% of them died. Autopsy revealed a mild edema and suggested that death was probably due to the acute anemia that followed the removal of blood. The withdrawal of from 60 to 80 cc. of blood from the right side of the heart of the animals of the third group and reintroduction of the blood into the right femoral artery saved all the animals except one. Two hypotheses are advanced to explain the mechanism of action of intracardiac blood removal from patients with pulmonary edema secondary to lung surgery or to heart disease. Either the excess flow to the lungs is decreased or a more normal ratio is established between the volume of blood in the systemic circulation and that in the pulmonary circulation. The author favors the second hypothesis, since removal of blood directly from the right side of the heart would, as a rule, reduce congestion of the pulmonary circulation better than removal of peripheral blood.

Cultivation of Koch's Bacillus from Laryngeal and Pharyngeal Swabs.—The sensitivity of the laryngeal and pharyngeal swab method of cultivation as compared with that of other routine methods used in detecting Koch's bacillus was studied in 100 patients at the Institute of Phthisiology at Montevideo. Control tests by direct examination and examination of gastric washings and sputum were made for each patient, followed by cultivation of material obtained on the same day by the use of laryngeal and pharyngeal swabs. Results were in agreement in 88 cases, 46 of which were negative and 42 positive. They disagreed in 12 cases, two being positive by the control tests and negative by the swab method and the other 10 being negative by the control tests and positive by the swab method. Inconvenience for the patient is minimal; fasting is not necessary and specimens may be taken at any hour of the day. The swabs, after having been used dry in order to collect as much material as possible, are treated first with sulfuric acid and then with sodium bicarbonate according to Adler's technique. The bacilli are cultivated on solid mediums, and secondary bacterial contamination seldom occurs. The whole procedure is simple and rapid, and may be used either for detecting new cases or for evaluating the effects of therapy in old ones.

Treatment of Vitiligo with Extract of Ammi Majus.—Patients with vitiligo may be treated with extracts of ammi majus given internally in tablet form and concurrently applied locally in a solution, or by either of these methods alone, combined with exposure to the sun or to ultraviolet rays. Irradiation is indispensable to repigmentation; pigmentation never appears in nonirradiated plaques. The results vary according to the patient's age and race; the duration, form, and site of the disorder; the regularity of the treatment; and, especially, the nature of the irradiation (the wave lengths should be between 2,900 and 4,077 Å.). Young children and adolescents, even those with extensive lesions, respond much more rapidly than adults. The rapidity of the response in all patients is directly related to the frequency of the irradiations; when the lesions are irradiated daily, repigmentation appears promptly and increases progressively. Tolerance for the medication taken internally is good; nausea, insomnia, and nervousness may occur, but soon disappear or diminish. The drug is available in 7.5 mg. tablets of xanthotoxine (ammoidine) and 2.5 mg. tablets of Impératorine (ammidine). It should not be given to patients with hypertension, hepatic disorders, or cardiac or renal insufficiency because repeated doses have a toxic effect on the liver. Dosage consists of 3 or 4 tablets a day (½ to ¾ mg. per kilogram of body weight), and patients are instructed to discontinue ingestion of the drug for one week each month. Normal alcoholic solutions contain 10 mg. of xanthotoxine or 5 mg. of Impératorine per cubic centimeter, while weak solutions contain half as much. Periods of irradiation must not exceed one-fourth to one-half minute at first, and should be increased very gradually. Lesions on exposed surfaces must be protected from light following irradiation. The results of the treatment are greatly influenced by the length of time between the application of the solution and the irradiation; the more time the solution has to penetrate the skin, the greater is its photocatalyzing effect. Local application may produce photosensitization or phototrauma. Phototrauma, which is caused by overexposure and occurs 24 to 72 hours after irradiation, is characterized by erythema, with or without edema, and blisters. Fever (40 to 41 C), nausea, vertigo, headache, and transient anuria may also be present. Treatment may be resumed after the subsidence of these reactions, which occurs rapidly under local care. Photosensitization, on the contrary, is an absolute contraindication to local application of ammi majus; it is infrequent, but should be recognized, because the eczema it causes may become generalized. Ammi majus therapy has produced a favorable response in 84 of 106 patients treated in the last two years: 7 are cured, 10 almost completely repigmented, 17 improved, and 50 show signs of repigmentation.

*New Method of Diagnosis for Hemophilia: Assay of Antihemophilic Factors A and B. J.-P. Soulier and M.-J. Larrieu.—p. 205.
Physiopathology of Acute Leukemia Under Treatment. J. Bernard and G. Mathé.—p. 216.

Assay of Antihemophilic Factors A and B in Hemophilia.—Patients with hemophilia may be divided into two groups: (1) those lacking the classic antihemophilic factor, A, and (2) those lacking a new factor, B, that possesses the same characteristics as that called the plasma thromboplastin component by Aggeler and associates, that described by Schulman and Smith, and that identified by Biggs and co-workers as the "Christmas factor." Prothrombin consumption and heparin tolerance are disturbed in all the anomalies affecting the first stage of coagulation; consequently, tests based on these functions are not specific for hemophilia. A new test provides a simple, specific, and sensitive method of determining antihemophilic activity of either type A or B. It is simple, because the reagents are always available; specific, because variations due to platelets are eliminated; and sensitive, because changes in the antihemophilic factors, which are disturbed even in mild forms of genuine hemophilia, are clearly reflected. In the test for factor A the following reagents are used: (1) human hemophilic plasma deficient in factor A and freed from platelets and thromboplastin by prolonged centrifugation at a low temperature (reagent A); (2) a platelet extract deprived of antihemophilic activity (A) by being kept at a temperature of 38 C for 30 minutes; and (3) the plasma to be tested diluted 1:20 with isotonic sodium chloride solution or a buffered medium immediately before the test. Control plasma is prepared in the same manner. Four tubes, placed in a water bath at 37 C, are filled as follows: (1) 0.1 cc. of reagent A, 0.1 cc. of platelet extract, 0.1 cc. of the plasma to be tested, and 0.1 cc. of a calcium solution (1.11 gm. of $CaCl_2$ per 400 cc.); (2) 0.1 cc. of reagent A, 0.1 cc. of platelet extract, 0.1 cc. of control plasma, and 0.1 cc. of calcium solution; (3) 0.1 cc. of reagent A, 0.1 cc. of platelet extract, 0.1 cc. of isotonic sodium chloride solution or a buffer, and 0.1 cc. of calcium solution; and (4) 0.1 cc. of A reagent, 0.2 cc. of isotonic sodium chloride solution, and 0.1 cc. of calcium solution. The coagulation times in the four tubes are compared. If the clotting defect evident in the hemophilic plasma is not corrected by the plasma being tested as it is by the control plasma, then the test plasma is deficient in factor A. Twelve of 18 hemophilic patients tested by the authors had less than 8% of the antihemophilic factor A. The new factor, B, was detected in a boy of 16 who had all the symptoms of familial hemophilia but whose blood was not deficient in factor A. Tests proved that the factor responsible existed in normal plasma and plasma treated with bishydroxycoumarin and also in normal serum. It resisted heating for 5 minutes at 56 C, but was destroyed at 64 C (partially in 5 minutes, completely in 20). It passed through Seitz filters of 20% asbestos but was retained by those of 50%, and was adsorbed by barium sulfate. Plasma from a patient with A-deficient hemophilia and that from one with B-deficient hemophilia were reciprocally corrective. A test for antihemophilic factor B, similar to that for factor A, uses 0.1 cc. of B-deficient hemophilic plasma, 0.1 cc. of platelet extract heated for 30 minutes at 64 C (this removes factors A and B), 0.1 cc. of the plasma to be tested, diluted 1/20, preferably in a buffer, and 0.1 cc. of $CaCl_2$ M/40. In these conditions, a patient with A-deficient hemophilia will have a clotting time equal to that of a control, while one with B-deficient hemophilia will have a prolonged clotting time.

*Hydralazine in Hypertension; Clinical Study. A. F. Essellier, W. Lüscher and L. Morandi.—p. 340.

Hydralazine in Hypertension.—Of 125 patients with hypertention, 76 were treated with hydralazine (Apresoline) and 49 were treated with 1,4-dihydrazinophthalazine (Nepresol). Of the first group of 76 patients, 11 were given intravenously single doses of 15 to 200 mg. of the drug diluted in isotonic sodium chloride solution, 11 were given intramuscularly single doses of 15 to 30 mg. of the undiluted drug, 17 with essential hypertension and 14 with nephrogenic hypertension received orally single doses of 200 to 350 mg., and 17 patients with essential hypertension and 6 with nephrogenic hypertension were given orally 75 to 900 mg. in three to four divided doses daily for 6 to 53 days. A definite drop of blood pressure resulted from the parenteral administration of hydralazine in 90% of the patients with nephrogenic and with essential hypertension. Oral administration of single doses of the drug was effective only in 70% of the patients, and those with nephrogenic hypertension seemed to respond less satisfactorily. The effective single parenteral dose varies from 20 to 40 mg. as compared to 25 to 100 mg. for the oral dose. The degree of the hypotensive effect of the drug cannot be increased by increasing the dose. On parenteral administration, the drug exerts its effect within several minutes, while the latent period after oral administration is much longer and varies considerably with the individual patient. The duration of the effect varies between 30 minutes and 10 hours independently of the route of administration. A much higher dose is required orally than parenterally to obtain the same duration of effect. Untoward side-effects, such as headache, nausea, and vomiting, particularly with parenteral administration, occurred in two-thirds of the patients. Since the hypotensive effect of the drug does not last longer than six hours, oral administration is the only method for continued treatment, but frequent and unpleasant untoward reactions make continued treatment with hydralazine difficult. Of the 49 patients treated with 1,4 hydrazinophthalazine, 25 were given single doses of 25 to 100 mg. in tablet form, and 24 received 25 to 750 mg. in two to four divided doses daily for 4 to 82 days. A definite hypotensive effect was obtained with single oral doses in three-fourths of the patients with essential hypertension and in one-half of the patients with nephrogenic hypertension. The threshold dose lies between 25 and 50 mg. The hypotensive effect occurred rapidly, mostly within 15 minutes, and it lasted for from 1½ to 10 hours and occasionally more than 24 hours. The depressive effect could not be regularly increased by increases of the dose, but its duration was somewhat prolonged. In some patients the effect of the drug varied with the same dose, and it was not always possible to prevent a new increase of blood pressure by repeated doses of the drug. A drop of 20 to 45 mm. Hg of the diastolic pressure was obtained with continued administration of 25 to 750 mg. of the drug daily in half of the patients with essential hypertension, while there was less response to the drug among the patients with nephrogenic hypertension. Untoward reactions to 1,4 dihydrazinophthalazine were less frequent and less unpleasant than those to hydralazine; occasionally they subsided despite continued treatment or after temporary reduction of the dose of the drug. Treatment had to be discontinued because of intolerance in one-eighth of the patients. The authors conclude that continued treatment of hypertensive patients with hydralazine or 1,4 dihydrazinophthalazine results in a drop of blood pressure in about half of the cases, but it does not restore the pressure to normal. Patients with essential hypertension respond better than those with nephrogenic hypertension. Side-effects are frequent and unpleasant but always reversible. The 1,4 dihydrazinophthalazine is somewhat superior to hydralazine in its effect. These interesting but not always therapeutically effective agents are still in the stage of clinical trial.

Total Hypophysectomy in Treatment of Cancer. J. Le Beau and M. Perrault.—p. 1096.

*Hemispherectomy and Epilepsy: Electroencephalographic Studies. M. Feld and R. Lecasble.—p. 1104.

Hemispherectomy and Epilepsy.—Hemispherectomies were performed on two boys and two girls between the ages of 3½ and 15 years with jacksonian epilepsy. In all four cases pneumoencephalographic studies had revealed atrophy of one cerebral hemisphere, with total dilatation of the corresponding lateral ventricle. In each patient electroencephalographic recordings were made before, during, and after the surgical intervention. As a result of their observations the authors state that bilateral abnormal electrical activity manifested before the hemispherectomy is not a contraindication to the surgical intervention, provided that both the clinical and the roentgenologic findings indicate the surgical intervention. The abnormal electroencephalographic activity observed in two of the authors' patients in the nonatrophic hemisphere before the operation, proved after the operation to have been projected from the atrophic hemisphere; this activity, therefore, must be considered only as repercussion despite the fact that in one of the patients the chronological and morphological characteristics of this activity seemed to be autonomous. While preoperative electroencephalographic recordings did not reveal gross anomalies in one of the patients, the electrocorticogram (with the electrodes placed directly on the cortex) revealed a focus in the left frontal region with spikes and delta rhythm. Significant divergences between the preoperative electroencephalogram and the electrocorticogram may, therefore, be expected. Electroencephalographic recordings taken from the hemispheric stump after the removal of the pallium revealed a residual epileptic activity, localized in one patient in the insula, in another patient in the tail of the caudate nucleus, and in a third both in the insula and in the caudate nucleus. In such cases surgical intervention should be completed by removal of the structure with abnormal electrical activity. Results obtained by adhering to this rule showed that the patients did not have additional functional deficiency. Postoperative electroencephalographic recordings revealed a small amplitude of the tracings obtained from the half of the scalp corresponding to the side operated on. The tracing obtained from the remaining hemisphere resumed its normal character; the previously recorded epileptic activity had disappeared. The small amplitude of the tracings on the operated side as projected by the opposite hemisphere becomes larger at a later period.

*Internal Anal Sphincter: Its Surgical Importance. S. Eisenhammer.—p. 266.

Surgical Importance of the Internal Anal Sphincter.—According to Eisenhammer, the internal sphincter plays a leading role in the normal functioning of the anal canal. It is a continuation of the circular muscle coat of the rectum and is composed of unstriated smooth muscle that shows continuous involuntary postural tone. Like the involuntary smooth circular muscle of the alimentary tract, the internal anal sphincter is predisposed to spasm. It has been widely accepted that the division of the internal sphincter will give rise to anal incontinence. The author, however, emphasizes that, if a normal internal sphincter is divided, no postoperative spasm can occur and, when healing is completed, the anatomical variation is infinitesimal. If a contractured fibrotic muscle is divided, the initial separation is far greater and, on healing, normal expansibility and dilatation is restored. The slender subcutaneous external sphincter must be carefully preserved, as it guards against a patulous or gaping anus. The author describes and illustrates with diagrams the technique of internal anal sphincterotomy. He regards the following as indications for this operation: senile anal contraction or spasmodic stricture, postoperative stenosis, congenital stenosis, chronic anal fissure, hemorrhoids with or without a chronic fissure where contracture of the sphincter is present, uncomplicated hemorrhoids, anorectal abscess, low-lying intrarectal tumors, and constipation due to contraction of the internal sphincter. He calls attention to misunderstandings about the pecten band, which he defines as the lower free border of the internal sphincter that has undergone the changes described as chronic internal anal contracture. He stresses that an understanding of the surgical significance of the internal sphincter must lead to a better anatomical approach to the surgery of the anal canal.

Farmer's Lung.—Fuller says that the terms farmer's lung and thresher's lung are synonymous. He has observed 32 patients with this disorder during the past eight years. Farmer's lung occurs in three forms: (1) the acute isolated attack, (2) the subacute and more chronic condition, which usually terminates in spontaneous recovery, and (3) the chronic and irreversible phase, in which secondary lung changes such as emphysema and fibrosis have occurred as a result of repeated exposures over a period of years. Five of the 32 patients had short acute attacks, 24 were in the subacute phase, and three had chronic pulmonary damage. Farmer's lung seems to be due to the inhalation of dust from moldy hay or straw. It has been suggested that this disease might be a true bronchomycosis and that Candida albicans might be the causal fungus, but Fuller says the evidence is far from conclusive. If farmer's lung were due to a bacterial infection, it would seem reasonable to expect that microscopy and sputum cultures would reveal some recurrent and constant infecting organism, which has not been the case. A third possibility is that farmer's lung is a form of asthmatic response to sensitization either by the degradation products of moldy grass or to molds themselves. If by asthma one means bronchial edema and spasm, accompanied by forced expiratory effort and sibilant rhonchi, then farmer's lung is not asthma. The fourth possibility is that farmer's lung is the result of irritation of the bronchial epithelium by the breakdown of mold spores and possibly grass particles resulting in miliary inflammatory response. Repeated exposure to hay or threshing dust with a high mold spore content eventually might produce in the bronchial wall a lesion resembling fungal granuloma in rabbits. Histological material from human subjects is difficult to obtain, because farmer's lung is almost never fatal. The one death that occurred in this series was in a patient who two years previously had had an attack of farmer's lung with spontaneous recovery. Necropsy showed widespread pulmonary tuberculosis. Neither culture nor microscopy of the lung tissue showed evidence of bronchomycosis. Many questions about farmer's lung remain unanswered, and the author suggests further studies.

*Vagotomy Combined with Simple Suture as Surgical Treatment for Perforated Gastric and Duodenal Ulcers. R. Jelinek.—p. 245.
Therapy of Hypertension. E. Hueber.—p. 248.
Processes of Myomalacia in Cardiac Auricles. P. Hermanek.—p. 248.
Relief of Pain in Incurable Carcinoma of Genitals. H. Tischer and J. Reitinger.—p. 252.

Vagotomy Combined with Simple Suture for Perforated Ulcers.—Between 1947 and 1952, 8 men with perforated ulcers of the stomach or duodenum were treated by simple suture followed by primary vagotomy and 16 were treated by suture or drainage and formation of an omental cuff followed by secondary vagotomy one and a half months to six years later when a new ulcer occurred. Length of postoperative hospitalization averaged 22 days in the first group and 19 days in the second group. Most of the patients were followed up for four to five years. Of the eight patients with primary vagotomy, six (four with gastric and two with duodenal ulcers) became completely free of complaints and their working capacity was fully restored. One of the remaining two with duodenal ulcers complained of vagus diarrhea and in the other carcinoma of the stomach developed but probably had no causal relationship with his former condition. One of the 16 patients with secondary vagotomy was lost to observation. Of the remaining 15, 9 were operated on for duodenal ulcer and 6 for gastric ulcer and 13 of them submitted to follow-up examination. Nine of the patients were free of complaints, and eight of these nine had been operated on for duodenal ulcer. Of the remaining four patients, gastritis was demonstrated on roentgenologic examination in two and a deformation of the duodenal bulb in one, while no pathological changes were observed in the last patient who complained of diarrhea. One of the 16 patients with secondary vagotomy died of pulmonary embolism on the third postoperative day. Because of the risk of malignant degeneration of ulcer of the stomach, the author is no longer using vagotomy for treatment of perforated gastric ulcer. As a result of his experience in this small group of patients, he feels justified in recommending vagotomy for further trial in certain cases of duodenal ulcer because of the simple technique, the small burden on the patient, and the low mortality. Diffuse peritonitis is the only contraindication to the method.

BOOK REVIEWS

Human Factors in Air Transportation: Occupational Health and Safety. By Ross A. McFarland, Ph.D., Associate Professor of Industrial Hygiene, Harvard School of Public Health, Cambridge, Mass. Cloth. $13. Pp. 830, with illustrations. McGraw-Hill Book Company, Inc., 330 W. 42nd St., New York 18; 95 Farringdon St., London, E.C.4, 1953.

This timely and significant book makes available to the medical profession an authoritative analysis of an important subject. A wide range of information from the biological and engineering sciences has been integrated with the specific problems of aviation medicine and flight safety. The treatment is broad in scope, and the data are applicable to both civilian and military flying and to industry in general.

Beginning with the selection of men for flight training, a wealth of source material of interest to the general practitioner has been reviewed and interpreted. The various tests in the most exacting of all physical examinations are related to the requirements of the job. Such a functional interpretation of a physician's findings may aid in the placement of personnel and in prolonging the useful lives of workers in many other occupations. Dr. McFarland points out that all the problems of flying cannot be answered by the aeronautical engineer. Indeed, the limiting factors in flying are in the capacity of the human organism to adapt to tremendous variations in altitude, acceleration, and prolonged periods of intense concentration. The great value of periodic health examinations is clearly illustrated by many case studies. Chapters on the maintenance of physical and psychological fitness, operational fatigue, and aging should aid the physician in handling many problem cases.

Other chapters of particular interest to physicians deal with the sanitary control of airports and ground facilities and health and quarantine regulations in air travel. An analysis of the problem of transportation of disease or disease vectors by aircraft is included. Since passengers can be conveyed from an infected to an uninfected area during the incubation period of the major communicable diseases, every physician should be aware of these dangers of air travel.

With the tremendous increase in air transportation, the physician is confronted with problems relating to the advisability of air transport for patients with various disabilities. Dr. McFarland has made many suggestions regarding the care and welfare of patients traveling by air. This thorough analysis of the physical and physiological problems encountered in flight, illustrated with case material, should aid the physician in making decisions regarding individual patients.

The chapter on the effective development of medical and safety departments in air transportation provides an excellent model for many other industries. It would be difficult to find a more convincing case for the great values to be derived from applying modern medical procedures to industry.

While this book can be read profitably by aviation medical specialists, the author's comprehensive approach to the subject of occupational health and safety recommends it as an important reference source for the physician. Excellent illustrations and summarizing paragraphs at the conclusion of each chapter enhance the usefulness of the book.

Fundamentals of Clinical Cancer with Emphasis on Early Diagnosis and Treatment. By Leonard B. Goldman, M.D., Clinical Professor of Radiotherapy, New York Medical College, Flower and Fifth Avenue Hospitals, New York. Cloth. $8.75. Pp. 312, with 222 illustrations. Grune & Stratton, Inc., 381 Fourth Ave., New York 16, 1953.

This book is merely a collection of material that has been published repeatedly; there is nothing new or original in the presentation or approach. The author states in the preface that some may take exception to the absolute statements and conclusions he presents but that his conclusions are the results of his own experience in treating cancer patients during the past 20 years. It is, nevertheless, dangerous to state as fact subjects that are controversial. For example, Paget's disease of the breast is dismissed in a mere four lines; it is specifically referred to as "an outward extension of a deeply seated cancer of the breast." Many would take issue with this statement. With regard to aspiration punch biopsy the author states that the capsule is not broken and no infection is introduced. In the next sentence, however, he states that a minute nick in the skin is made over the tumor. This not only breaks the capsule but may introduce infection; furthermore, the possibility of missing a small malignant zone by use of this method is not mentioned. The statement that early cancers may be removed by simple surgery while invasive cancers should be eradicated by radical surgery might be challenged. Some authorities on cancer surgery would take a diametrically opposite view.

Since this work deals with fundamentals of diagnosis, some mention should have been made of the differentiation of cardiospasm from cancer of the esophagus. Although figure 106 on page 122 shows the relaxation of the spasm after administration of amyl nitrite, the roentgenograms are so poorly reproduced that no differentiation can be made.

Figure 110 on page 127 is a poor example of art work; figure C of this illustration appears to be the ulcerating rather than the infiltrating lesion. On page 149 the statement is made that the gallbladder is palpable in cancer of the extrahepatic ducts "because the common bile duct is obstructed." This is a poor explanation, since the common bile duct is also obstructed when a stone is present, yet the gallbladder is small. No attempt is made to differentiate these two conditions or to explain the pathophysiology that results in the small inflamed gallbladder as compared to the noncicatrized organ, which is distendable.

Chapter 7 dealing with tumors of the breast is poorly presented. Both skin retraction and nipple retraction are stated to be caused by "fibroblastic reaction." This is evasive and confusing, particularly since no mention is made of the importance of the involvement of Cooper's ligaments and the lactiferous ducts as pertaining to these phenomena. Figure 155 demonstrates gentle palpation of a nodule in the breast for the purpose of demonstrating dimpling. Since tactile sensation and gentleness are important, one wonders why the examiner's hand is gloved. The subject of mammary dysplasia is presented under the old terminology of cystic hyperplasia (chronic cystic mastitis). It is impossible to dismiss such a subject in less than 10 lines. Greater attention to detail and arrangement of material might have improved this work.

The Management of Abdominal Operations. Edited by Rodney Maingot, F.R.C.S. Cloth. $24. Pp. 1253, with 532 illustrations. The Macmillan Company, 60 Fifth Ave., New York 11, 1953.

This volume is directed to "postgraduates . . . senior resident medical and surgical officers. . . . Fellowship candidates . . . the general surgeon and those who are desirous of keeping abreast with developments in this field." The editor is one of Britain's outstanding surgeons, well-known in America for his previous books and writings, and his collaborators are 32 other British authorities. The manner of presentation is most successfully carried out in that this work of 33 different writers is coherent and uniform throughout in its point of view. The book is a summation of everything that concerns abdominal operations and reads like an informal, concise discussion by an authority. The authors assume that the reader is conversant with classical symptomatology and minutiae of operative technique; thus he does not have to reread standard material to obtain a new or important point. This forthright presentation permits a mature discussion, for which the authors and editor deserve great praise.

Another outstanding feature is the inclusion of the latest advances associated with major abdominal surgery. There are excellent chapters on fluid and electrolyte balance, surgical

---

The reviews here published have been prepared by competent authorities and do not represent the opinions of any official bodies unless specifically stated.

shock, chemotherapeutic and antibiotic drugs in abdominal surgery, the role of vitamins in abdominal surgery, abdominal injuries, and abdominal operations in children. Discussions of the internist's point of view are included when pertinent. The chapter on clinical and pathological values in health and disease is of practical value to the busy surgeon who has not been close to the laboratory where rapid advances are taking place. In keeping with progress is a chapter on psychological factors in abdominal surgery; this is not a perfunctory discussion in generalities but an excellent presentation in concrete terms.

No large work can possibly include every detail, and this one contains certain omissions and disagreements. In the chapter on biliary tract disease, no mention is made of Phemister's classical work on the etiology of calcareous deposits or calcified gallstones (cystic duct obstruction), although beautiful illustrations of calcified gallstones are shown. Too little is said of the patient who is just as ill after cholecystectomy as he was before. All surgeons would not agree that "the Talma-Morrison operation now has no place in the treatment of ascites, etc."; no mention is made of preoperative "chronic shock," i. e., reduced blood volume; venous pressure receives scant mention in connection with shock, and the only blood substitute mentioned is acacia (gum arabic). In the chapter on psychological factors are the statements: "If a patient asks and is told he has the disease [cancer] . . . Nothing is to be gained by deliberately lying to the patient." Many persons of experience believe that in no circumstances should a patient be told he has cancer. The family, or close friends if there is no family, of course, must be told the complete truth.

The appearance of the book is most attractive. The paper is of excellent quality, the large print agreeable to the eye, the tables and figures informative, and the illustrations are of the highest quality. This work is recommended as a reference and textbook for those doing abdominal surgery. The book will serve to crystallize thinking in this field and present new facts and stimulating ideas. It is a comprehensive postgraduate course in abdominal surgery that will not become outdated for some time.

Comroe's Arthritis and Allied Conditions. Editor: Joseph Lee Hollander, M.D. Collaborating editors: Nathan R. Abrams, M.D., et al. Fifth edition. Cloth. $16. Pp. 1103, with 399 illustrations. Lea & Febiger, 600 S. Washington Sq., Philadelphia 6, 1953.

Owing to the rapid advances made in the field of rheumatology in recent years, there has been a real need for revision of this book. This has been eminently accomplished in the present edition. The editor and the 17 collaborators are experienced rheumatologists, some of whom have been outstanding in clinical and investigative work. In addition to the basic information that this textbook has always contained, the more recently developed concepts in the field of rheumatology are included. For the most part the original format has been retained, including the helpful summaries in box form. Numerous excellent illustrations have been added. The bibliographies at the close of each chapter are extensive and in most instances include recent references. The style is uniform and easy to follow.

The book has 10 parts, about half of which are devoted to etiology, pathology, and treatment of rheumatoid arthritis. The remainder of the book concerns rheumatoid spondylitis, degenerative joint disease, collagen diseases, gout and other forms of metabolic arthritis, arthritis due to specific infections, traumatic arthritis, painful back, and arthritis associated with uncommon diseases. Proper emphasis is placed on the commoner types of arthritis, with brief discussions on the less common musculoskeletal diseases.

The new chapter on etiology of rheumatoid arthritis contributes a great deal of new thought in this field. The chapters on corticotropin, cortisone, and the intra-articular injection of hydrocortisone reflect the present concept and use of these hormones. There is none of the early hope for a miraculous cure or fear of permanent harmful effects from administration of these steroids; instead, there is a realistic appraisal of the benefits and limitations of the hormones in the treatment of rheumatoid arthritis and other rheumatic conditions. The chapter of low back pain and sciatica is a valuable addition covering anatomy, salient points in the history and physical examination of low back strain, and herniation of the intervertebral disk. Summaries in box form would have added to the value of the chapter, and its contents could have been developed more fully. This book remains the best authoritative volume on arthritis and allied diseases. It is highly recommended to students of rheumatology, internists, general practitioners, and undergraduate students.

Poliomyelitis. By W. Ritchie Russell, C.B.E., M.D., M.A., Consultant Neurologist to United Oxford Hospitals, Oxford, England. Cloth. $3. Pp. 84, with 20 illustrations. Williams & Wilkins Company, Mount Royal and Guilford Aves., Baltimore 2; Edward Arnold & Co., 41-43 Maddox St., London, W.1, 1952.

This small volume can be read in a single evening, and it should be a rewarding and interesting experience for any physician who wants a quick "refresher course" on the aftercare of poliomyelitis. The author, unlike most neurologists interested in poliomyelitis, is concerned with clinical aspects of this disease beyond the central nervous system. The book reflects the fact that Dr. Russell has a wide and general clinical experience with poliomyelitis and has followed patients not only in the role of a neurological consultant but as a physician in charge of the case; that is, from the time his patients have come into the hospital, through the anxious period of acute illness, through the infectious stage, and throughout subsequent months or years in cases with paralysis. In this respect he has demonstrated how a neurologist often can give continuity to the therapeutic team and can occupy a position as an intermediary with the internist, the orthopedist, and the physical therapist.

The first half of the book concerns the nature of poliomyelitis, its clinical features, physical examination, and some of the etiological factors. The second half describes management and treatment and reflects the author's experience in handling serious cases of poliomyelitis.

Two points that have not received enough emphasis in the U. S. deserve mention. One is the theory that postural drainage is a simple measure often neglected in the care of patients with respiratory paralysis and/or bulbar involvement. The author is convinced that the use of proper posture for the patient is vitally important and should not be delayed. The other point is his belief that the treatment of paralyzed limbs need not be dominated by the rule that weak muscles should always be rested in a partially relaxed position. He does not believe that deliberately induced fatigue harms paretic muscles in the recovery stages of poliomyelitis. If one is willing to accept this point of view, the value of various methods of handling paralyzed muscles can be subjected to simple physiological tests to compare the results of grossly different plans of treatment.

Diagnostic Tests in Neurology: A Selection for Office Use. By Robert Wartenberg, M.D. Forewords by Sir Gordon Holmes, M.D., F.R.S., and by Stanley Truman, M.D. Cloth. $4.50. Pp. 228, with 62 illustrations. Year Book Publishers, Inc., 200 E. Illinois St., Chicago 11, 1953.

Dr. Wartenberg has justly deplored the overemphasis on neurological diagnosis by laboratory methods, many of them inappropriate and, at times, misleading. His view is well expressed by quotation from Balfour: "I very much doubt if the modern doctor with the laboratory at his back . . . is as good at the bedside . . . as those who have had to trust to their powers of observation." Nowhere is that truer than in the field of neurology. Yet a losing battle is being fought; there is an ever increasing tendency to join Foster Kennedy's "Union of Slick Gadgeteers."

In this short monograph the author has discussed a number of simple clinical tests that are of value in demonstrating disorders of the nervous system. Whether such a disconnected presentation of a group of signs and tests is of value each reader must determine for himself. Neurology, however, is not "reflexology," and this book, as the author has stated, is a systematic presentation of neurology correlated with basic anatomy, physiology, and pathology.

Some of the author's premises are questionable. His discussion of the unilateral dilatation of the pupil, which develops after head injuries (page 37), is incorrect. Dilatation seldom is due to pressure of a blood clot on the third nerve. In fact, with an extradural hemorrhage arising from the middle meningeal artery, that could not occur. Usually the uncus herniating through the incisura of the tentorium cerebelli involves the third nerve. Furthermore, such a mydriasis, with or without a hemiparesis, may develop as the result of a subdural hemorrhage as well as with bleeding from the middle meningeal artery. Most neurologists would not agree that a slow, coarse nystagmus on looking to one side is primarily indicative of a cerebellopontine angle tumor (page 43); in fact, an intracerebellar tumor is more likely. Although the author has recognized that many so-called pyramidal signs are associated with lesions of the extrapyramidal system, he seems to have promoted this confusion rather than clarified it (section 3). There are a limited number of references in the text, but there is no bibliography.

Pathologie und Bakteriologie der Endokarditis. Von R. Böhmig und P. Klein. Cloth. 66 marks. Pp. 312, with 104 illustrations. Springer-Verlag, Reichpietschufer 20, (1) Berlin W. 35 (West-Berlin); Neuenheimer Landstrasse 24, Heidelberg; Göttingen, 1953.

This book represents the combined efforts of a pathologist and a bacteriologist and is based on the examination of 300 cases of endocarditis observed at necropsy. There are, consequently, few clinical considerations. After presentation of the general pathology of endocarditis and normal anatomic changes, bacteriology is discussed, including questions of technique and emphasis on the classification of streptococci. This is followed by a chapter on the particular pathological anatomy and bacteriology of endocarditis. The classification differs from that accepted in the U. S., and emphasis is given to serous endocarditis as a manifestation of inflammatory edema. Principles of antimicrobial therapy are also discussed in this chapter. A short chapter deals with transition of the different types of endocarditis and the attempt to present an organized scheme. Another chapter concerns experimental endocarditis and the observations of the investigators. The final chapter, mainly speculative, presents the results and conclusions applicable to clinical medicine. The presentation attempts to integrate the recent American concepts of endocarditis and collagen diseases with the older German studies, and the American literature is well represented. A considerable amount of factual information is intermixed with remote philosophical concepts, which, as such, seem to add little to the understanding of pathological processes. This difficulty is aggravated by an awkward style and lengthy, sometimes incomprehensible, sentences. The illustrations are excellent. The book has limited value for the American clinician or pathologist and may serve best to illustrate the German position on the pathology of endocarditis.

Blood Cells and Plasma Proteins: Their State in Nature. Edited by James L. Tullis. Memoirs of University Laboratory of Physical Chemistry Related to Medicine and Public Health, Harvard University, number 2. Cloth. $8.50. Pp. 436, with illustrations. Academic Press, Inc., 125 E. 23rd St., New York 10, 1953.

This book records a series of seminars on the physical chemical characteristics and biological properties of blood and plasma. The book is divided into seven sections covering the formed and fluid parts of human blood; their discovery, characterization, and classification according to physical properties and chemical interactions; factors concerned with blood coagulation; components of human blood concerned with immunity; erythrocytes; leukocytes; enzymes of the plasma; and lipoproteins and glycoproteins of blood and tissues. The subjects are discussed by a number of authorities, and many charts, tables, and diagrams illuminate the text.

The material in this volume is highly important in view of the increasing use of various fractions of human blood in the practice of medicine. The inclusion of historical background in some of the sections, particularly in that presented by E. J. Cohn, is commendable. Part of the material is highly technical and is meaningful primarily to those who have a special interest in the chemical aspects of the subject. On the other hand, a large portion of the book is of general medical and biological scope and importance and is understandable without special knowledge of physical chemistry. For example, the sections on the blood clotting system, the immune globulins, and the lipoproteins present many of the current theories. This book is recommended to anyone interested in keeping abreast of modern developments in medicine and its allied fields.

Famine Disease in German Concentration Camps: Complications and Sequels, with Special Reference to Tuberculosis, Mental Disorders and Social Consequences. By Per Helweg-Larsen, et al. Supplementum 83, Acta psychiatrica et neurologica scandinavica. Paper. Pp. 460, with 25 illustrations. Ejnar Munksgaards Forlag, Nørregade 6, Copenhagen, K, 1952.

This monograph is a valuable clinical description of famine disease as the syndrome was reported by 1,282 Danes who survived internment in German concentration camps during World War II. It pictures the macabre conditions under which starvation occurred and recognizes the difficulty of separating the effects of psychic trauma from nutritional factors that contributed to the syndrome of famine disease. Of special merit are the sections dealing with hunger edema, polyuria, hunger diarrhea, alimentary diarrhea, metabolism, avitaminoses, and mental deterioration. The record of treatment, emphasizing a dietetic regimen, will aid physicians in avoiding some of the errors that occurred during World War II as a result of a too sophisticated approach of clinicians to the supposed deficiency states in semistarved patients. The description of rehabilitation and the comments on the permanence of the famine-induced condition will be of interest to those concerned with rehabilitation of such persons. The 484 complete references in the bibliography enhance the value of the book. Study of this document is recommended to medical nutritionists, psychiatrists, internists, and others concerned with the care and rehabilitation of war prisoners.

Advances in Internal Medicine. Volume V. Editors: Williams Dock, M.D., and I. Snapper, M.D. Cloth. $10.50. Pp. 464, with illustrations. Year Book Publishers, Inc., 200 E. Illinois St., Chicago 11; Interscience Publishers, Inc., 2a Southampton Row, London, W.C.1, 1952.

This is a collection of nine authoritative review articles on topics of current interest in internal medicine. The reviewers summarize and interpret the results of recent investigations and discuss application of these results to clinical management. Extensive bibliographies are appended. The volume begins with a practical discussion of the diseases of the pregnant woman affecting the fetus. This is followed by a scholarly review of the technique and complications of cardiac catheterization and the information on circulatory dynamics gained by this procedure in various types of heart disease. There is a short discussion of the mechanism of production of portal hypertension and the various surgical approaches to its correction. The metabolic and pathological changes occurring in the anemia of infection and in gout are reviewed in detail, and the management of these conditions is outlined. Other chapters consider the clinical use of ganglionic and adrenergic blocking agents, clinical experiences with corticotropin and cortisone, and various aspects of the influenza problem. A final chapter deals with laboratory investigations of abnormal proteins in myeloma. The reviews are adequately indexed. Physicians interested in the subjects covered will find this volume a useful postgraduate refresher course and reference work.

Pain Syndromes and Their Treatment with Special Reference to Shoulder-Arm Pain. By James M. Tarsy, M.D., Chief, Arthritis Clinic, University (New York Postgraduate) Hospital, New York University-Bellevue Medical Center, New York. Cloth. $12. Pp. 592, with illustrations. Charles C Thomas, Publisher, 301-327 E. Lawrence Ave., Springfield, Ill.; Blackwell Scientific Publications, Ltd., 299 Queen St., W., Toronto, 2B, 1953.

This excellent book should be welcomed by all physicians, because pain probably represents about *50%* of patients' complaints. In this book, these problems are outlined mostly with respect to pain in the body; problems of pain in the head are not included. Considerable space is devoted to diagnostic and therapeutic blocks for pain. One of the outstanding sections of the book is an exhaustive consideration of diagnosis and treatment of shoulder-arm pain and other similar types of pain. The paper is of fine quality; the illustrations are excellent; and the index is adequate.

Cardano the Gambling Scholar. By Oystein Ore. With translation from Latin of Cardano's Book on Games of Chance, by Sydney Henry Gould. Cloth. $4. Pp. 249, with 33 illustrations. Princeton University Press, Princeton, N. J., 1953.

Girolamo Cardano of Milan was one of the fathers of medicine "next to Paracelsus and Nostradamus." He was born in 1501 and died in 1576, leaving behind 10 huge volumes containing information on many subjects. The son of a gifted father, Cardano was born out of wedlock, which barred him from membership in some of the learned societies. He was poor, but "When he finally began to make money he managed his affairs well, and above all he was a very popular physician with a great and universally recognized reputation" (page 34). Cardano was a student of all the sciences and philosophies and was a prolific writer on mathematics, astronomy, physics, ethics, religion, and philosophy. He also published a life of Christ and one of the Blessed Virgin. He was an egoist but confessed equally to vices and virtues and was "an enigmatic character" who, in the words of Bacon, "seems to have taken the whole world for his province." In some respects Cardano resembled Voltaire in his brilliance, his inconsistencies, and his utter unreliability; yet he had a certain sweetness and light that charmed many men but brought hate from others.

Professor Ore became interested in Cardano partly because of his attempt to rationalize gambling, to put "chance" on a sound basis with formulas and discussion of those "probabilities" that some of us first encountered in advanced algebra. The last section of the book is a translation of Cardano's "Liber de Ludo Aleae" or "Book on Games of Chance." This book is interesting and is exceedingly well put together.

Oral Anatomy. By Harry Sicher, M.D., D.Sc., Professor of Anatomy and Histology, Loyola University School of Dentistry, Chicago College of Dental Surgery, Chicago. Second edition. Cloth. $13.50. Pp. 529, with 310 illustrations. C. V. Mosby Company, 3207 Washington Blvd., St. Louis 3, 1952.

This is a concise, well-written, and accurate monograph on anatomy of the head and neck. The illustrations are good, and the type and format make for easy reading. The first section deals with basic anatomy and the second with its practical application. This section should be of interest to students and physicians alike. There are excellent discussions of the applied anatomy of local anesthesia blocks, arterial hemorrhages and their control by ligation, the spread of dental infections along anatomic planes, tracheotomy and laryngectomy, the temporomandibular joint, and the endentulous mouth. While this book was designed primarily for dentists, it should also be valuable to students and surgeons interested in head and neck surgery. A copy in every hospital medical library would be a practical aid to the intern and resident staff.

Ménière's Disease. By Henry L. Williams, M.D., M.S., Head of Section of Otolaryngology and Rhinology, Mayo Clinic, Rochester, Minnesota. Publication number 129, American Lecture Series, monograph in Bannerstone Division of American Lectures in Otolaryngology, Audiology and Broncho-Esophagology. Edited by Norton Canfield, M.D., Associate Clinical Professor of Otolaryngology, Yale University School of Medicine, New Haven, Conn. Cloth. $7. Pp. 349, with 8 illustrations. Charles C Thomas, Publisher, 301-327 E. Lawrence Ave., Springfield, Ill.; Blackwell Scientific Publications, Ltd., 49 Broad St., Oxford, England; Ryerson Press, 299 Queen St., W., Toronto 2B, 1952.

For many years the diagnosis and treatment of Ménière's disease have been difficult. Since Ménière's original description of the disease nearly a century ago, many conflicting opinions have been expressed regarding every phase of the entity. Most physicians are at a loss as to what procedure to follow when confronted by patients with vertigo, dizziness, tinnitus, incoordination, deafness, nausea, and vomiting. In an attempt to introduce order into this situation, the author has drawn on his extensive experience to describe in rational fashion such topics as anatomy and physiology of the labyrinth, histopathology and physiopathology, loss of hearing, diagnosis and differential diagnosis, allergy and autonomic dysfunction, and medical and surgical treatment. This book is an important contribution to medical literature and is highly recommended.

Oral Surgery. Volumes I and II. By Kurt H. Thoma, D.M.D., F.D.S. R.C.S. Second edition. Cloth. $30. Pp. 865; 867-1688, with 1789 illustrations. C. V. Mosby Company, 3207 Washington Blvd., St. Louis 3, 1952.

A wealth of new material has been presented in this edition. The author has incorporated chapters on local and general anesthesia and one on chemotherapy. Detailed consideration is given to abnormalities of the edentulous mouth and the combined oral and surgical prosthodontic problems. The chapter on surgical correction of developmental deformities involving the face and jaws includes new procedures. Two other chapters discuss acquired jaw defects and surgical deformities that require correction by means of grafts and the treatment of oral abnormalities and defects.

The chapter dealing with the general care of the patient is exceedingly well done. In the preface to the first edition, the author mentions that some might believe that the subject of supportive care has been overemphasized; however, Dr. Thoma believes that such overemphasis is rarely possible. The fact that controversial theoretical minutiae have been omitted is especially commendable. The chapter on treatment of traumatic disease of the jaws is outstanding because of the detailed yet terse manner in which the material is presented. As in the other chapters, the text reads well and can be easily assimilated.

The use of red coloring to depict submucous layers and cleavage planes aids the attempt to produce tridimensional perspective. It is unfortunate that the color did not reproduce well on some of the pages. In the chapter on anesthesiology the danger of infiltrating inflamed tissues is emphasized. Although this is an established fact, reemphasis is warranted. A minor fault is the method of labeling figure 1028. The names of the structures rather than letters should have been placed on the illustration. This work can be unreservedly recommended to anyone interested in oral surgery.

Clinical Obstetrics. By members of staff of Pennsylvania Hospital. Edited by Clifford B. Lull, M.D., and Robert A. Kimbrough, M.D., Director of Division of Obstetrics and Gynecology, Pennsylvania Hospital, Philadelphia. Cloth. $10. Pp. 732, with 400 illustrations. J. B. Lippincott Company, 227-231 S. Sixth St., Philadelphia 5; Aldine House, 10-13 Bedford St., London, W.C.2; 2083 Guy St., Montreal, 1953.

This book has been prepared by a number of specialists discussing the phases of their fields that are related to clinical obstetrics.

The management of the newborn in the neonatal period is well covered; and the discussion on the relation of roentgenology to the practice of obstetrics is well done and profusely illustrated. Anesthesia, both local and general, is described with possibly too much emphasis on spinal anesthesia for the teaching of undergraduate students. There are sections on sterility and fertility in both men and women and the influence of diet on pregnancy and the puerperium.

The book is well illustrated, and the type is clear and well spaced. It should be an excellent book for undergraduates beginning the study of obstetrics, postgraduates at the intern and residency level, and general practitioners who have obstetric problems.

Gastric Cancer. By Alfred H. Iason, M.D., Attending Surgeon, Adelphi Hospital, Brooklyn, N. Y. Cloth. $7.50. Pp. 316, with 100 illustrations by Alfred Feinberg, Instructor of Medical Illustration, Department of Pathology, College of Physicians and Surgeons, Columbia University, New York City. Grune & Stratton, Inc., 381 Fourth Ave., New York 16, 1953.

This monograph on gastric cancer represents a tremendous amount of work and is a good résumé of the current thinking on this subject. It is unfortunate that a book containing so much information does not give any of the author's experience and does not include more original illustrations. In fact, the work represents a compilation of the literature and contains an extensive bibliography, although an evaluation of the various concepts is not particularly well done. The book may be of value to the student because of the extensive bibliography, but it is not otherwise recommended.

QUERIES AND MINOR NOTES

VACCINATION OF CHILD WITH ECZEMA

To the Editor:—*A girl, 5 years of age, has had atopic eczema since the first year of life, the antecubital and popliteal areas being chiefly affected. Various substances have been used locally, with little benefit. The child has never been vaccinated against smallpox. It is my understanding that smallpox vaccination is contraindicated in the presence of eczema. Is there any method by which smallpox vaccination, which is required for admission to public school, can be done safely in this case?* *M.D., Washington, D. C.*

Answer.—It is not necessary to withhold smallpox vaccination from a child with localized atopic eczema. It is, however, desirable to vaccinate such a child at a time when the eczema is quiescent rather than during a flare-up. Also, reactions that are more apt to occur in a child with the atopic form than in one with a nonatopic form should be anticipated. A flare-up of the eczema may occur during the reaction to vaccination, with consequent increase of discomfort and necessity for resort to local treatment of the eczema. It is possible that a kaposiform eruption of the varicelloid or herpetic type will develop. Obviously, measures to prevent transfer of material from the site of vaccination to eczematous areas of the skin should be employed. In the young child who cannot be relied on to cooperate, protection by bandaging of affected areas may be necessary temporarily.

IODIDE AND BROMIDE ERUPTION

To the Editor:—*A pustular, acneform rash confined to the face, especially the nose, forehead, and chin, appeared in a 47-year-old man a few weeks after he began to use a bromine-containing hypnotic and an iodine-containing multivitamin and mineral preparation. The use of both these preparations was stopped when the eruption appeared, but several weeks have elapsed and the condition persists. What is the best treatment for this mild bromidism and iodism, topically and systemically? The patient's occupation makes it imperative that his appearance cosmetically be of the best. The only relevant past history is adolescent acne of the face of several years' duration, which cleared up following x-ray treatment. Would application of ultraviolet light help now?* *M.D., New York.*

Answer.—This eruption appears to be one of the typical manifestations of sensitivity to iodine or bromine or both. The most important therapeutic measure is to interdict the intake of iodine and bromine insofar as this is possible. This means elimination of drugs containing iodides and bromides, iodized salt, and the following foods, which contain large amounts of iodides: clams, crabmeat, lobsters, oysters, salmon, shrimp, red snapper, flounder, cod fish, asparagus, radishes, tomatoes, carrots, lettuce, the leafy vegetables such as kale, mushrooms, watercress, potatoes, and eggs. The second step in treatment is ingestion of large amounts of regular table salt, provided there is no contraindication, such as severe hypertension. This promotes the excretion of both iodides and bromides. The local treatment of the eruption should be similar to that used for acne vulgaris. A flesh-tinted sulfur and resorcin ointment, such as Acnomel or Sulforcin base, is satisfactory, and, in addition, these preparations tend to obscure the lesions and make the condition less conspicuous. Also, it may be advisable to open the individual lesions with an acne stilette. There is no contraindication to the use of ultraviolet light therapy, but it is doubtful that this would change the course of the eruption significantly.

FEVER IN THREE SIBLINGS

To the Editor:—*I am caring for four children who have resided in Kodiak, Alaska, within the past year. About nine months ago, all four were given BCG vaccine, because they had negative tuberculin test results. The three older children were told they had a successful vaccination, but the youngest had no reaction. At present, all except the youngest have daily temperatures ranging from 99.5 to 101 F. All appear relatively healthy and show no abnormal physical conditions. Roentgenograms of the chest were normal. Results of brucellosis tests, tuberculin patch tests, and intracutaneous old tuberculin tests are all negative. A trial course of antibiotic therapy produced no change in temperature. Could the BCG still be causing the fever?* *Russell E. Atkinson, M.D., Crestline, Calif.*

Answer.—The fact that the results of tuberculin tests are negative now rules out the BCG vaccine as a cause. If tuberculosis is the cause of the fever, the infection is recent, since allergy has not yet developed. The fact that the three children are febrile at the same time points more strongly to an intercurrent infection. Primary tuberculosis manifests certain symptoms in children that are not produced by other conditions, notably a fleeting morbilliform rash of varying degrees of intensity. Instead of clearing there is a dry, scaly residue that may remain for some time. Occasionally erythematous lesions may be present. Otherwise, there are no systemic symptoms. If the process is tuberculous, the tuberculin test should become positive within three months from the time of infection. The children's condition seems to be some obscure process that does not fit into the pattern of ordinary children's diseases. Rheumatic fever is a possibility, and it has been noted to occur in families, but in this family the possibility seems remote. Brucellosis should be searched for again. Infectious mononucleosis could explain the phenomenon. Blood cell counts should confirm or disprove presence of such a condition.

CANCER OF CERVICAL STUMP

To the Editor:—*Please discuss the incidence of carcinoma of the cervix following conization as compared with total hysterectomy. When there is technical difficulty in removing the cervix, is a combination of subtotal hysterectomy plus conization advocated?* *John P. Gifford, M.D., Vero Beach, Fla.*

Answer.—Most authorities agree that carcinoma of the cervical stump is not rare. In a study by Carter and co-workers (*Am. J. Obst. & Gynec.* **57**:37, 1949) on adenocarcinoma of the cervix, it was found that 22% of the cases occurred in women with cervical stumps. A report from the department of obstetrics and gynecology of Vercelli (Cantone, C.: abstracted, *Am. J. Obst. & Gynec.* **55**:543, 1948) stated that carcinoma of the cervical stump developed in 0.67% of the patients who had had previous supracervical hysterectomies. These and other reports plus the observations of this consultant confirm the belief that, if at all possible, total hysterectomy is the procedure of choice. It is realized that in some patients it is technically difficult, if not impossible, to remove the cervix, and in these a combination of subtotal hysterectomy and conization of the cervix is beneficial. Crossen (*Am. J. Obst. & Gynec.* **57**:187, 1949) used wide conization and believed that it combined well with abdominal surgery. He states that in patients in whom hysterectomy must be supravaginal instead of complete, conization is especially helpful in eliminating the menace of continuing cervicitis in the cervical stump. In his series, wide conization of the cervix definitely reduced the incidence of subsequent cervical carcinoma. None of the 1,005 patients with cervicitis had cervical cancer during the period of observation, which in some cases was as long as 14 years.

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any official bodies unless specifically so stated in the reply. Anonymous communications and queries on postal cards cannot be answered. Every letter must contain the writer's name and address, but these will be omitted on request.

EDEMA OF UNKNOWN CAUSE

To the Editor:—*A woman, aged 40, for a year has had intractable edema of the feet, legs, thighs, arms, and abdominal wall; ascites is present, also. There are no signs of pericardial or pleural fluid. The heart, an electrocardiogram, the urine, the blood urea nitrogen and glucose levels, the serum chloride, protein, albumin, and globulin levels, blood smears, and blood cell counts all are normal. Pitting on pressure is marked. The edema is severe enough to make ambulation difficult, and the patient has gained 35 lb. (15.9 kg.) in weight. There have been several remissions of the edema, but none that I could attribute to therapy. There are several abscessed teeth. Both breasts on palpation reveal apparently benign cysts, which have been present for about five months. One year ago, a cyst was removed, which was pathologically benign. The thyroid has several nodules 0.5 to 1 in. in diameter (20 years ago an adenoma was removed). There are no signs of thyroid toxicity. Two years ago, a cholecystectomy was done because of stones. Recovery has been good, and the patient is not on a restricted diet. A hysterectomy was done four years ago because of severe backache attributed to uterine fibroids; two moderately sized fibroids were found on operation. Mild postoperative menopausal symptoms were easily controlled with estrogens. No estrogen has been given in a year. Another peculiar condition is a localized area on each arm above the elbow, involving several square inches, of increased hair growth. Another physician administered thyroid without effect. I have given large doses of thiamine subcutaneously and mercurial diuretics subcutaneously, without effect. I attempted to give cortisone orally, but the first dose caused dizziness, and I stopped it. On the basis of the meager history given, do you have suggestions as to diagnosis?*

M.D., New York.

Answer.—The diagnosis of the disease underlying the edema in this case is difficult, since the findings reported seem to exclude cardiac, renal, hepatic, hypoalbuminemic, lymphatic, and other less common general types of edema. Scleredema might be considered, but this almost invariably involves the face, especially the eyelids, and is often associated with pleural or pericardial fluid. Furthermore, the usual prodromal symptoms of scleredema were lacking in this patient. There remain only the hormonal edemas. Of these, myxedema is probably excluded by the failure to respond to thyroid. Edema of ovarian or adrenal cortical origin may be diagnosed by careful clinical observation and urinary hormone assays for estrogens and 17-ketosteroids and other adrenal cortical hormones. The serum sodium concentration should be determined during the height of the edema and later during a remission, to detect possible dilution of sodium by retention of water due to excessive posterior pituitary antidiuretic hormone secretion. These studies are sufficiently complicated to require hospitalization in an institution equipped with research laboratories. If adrenal hormonal imbalance is indicated, a trial of cortisone treatment might be helpful; however, the diagnostic work-up should be completed first. Elephantiasis due to lymphatic obstruction rarely involves the arms, unless there has been operative destruction of lymphatic channels, and frequent spontaneous remissions would be extremely unlikely in this disease. Only a biopsy of an affected region could definitely establish this diagnosis.

SKIN PIGMENTATION IN INTERMARRIAGE

To the Editor:—*What is the pattern of inheritance of skin pigmentation in intermarriage between persons of white and Negro races? Does a colored offspring sometimes result from the mating of mixed parents who are phenotypically white?*

William R. Gabbert, M.D., Danville, Ky.

Answer.—Patterns of inheritance are usually based on the Mendelian law, but on the question of Negro-white relationship the information is meager and the opinions divergent, placing it in the field of speculation. Pearson was of the opinion that skin pigmentation inheritance does not operate under the Mendelian law but that the coloring of the offspring of this combination represents a blending. Using a more modern interpretation of the Mendelian law and the use of the color top to match colors, Davenport arrived at these conclusions: There is no pattern of inheritance of skin pigmentation. The coloring of the first generation offspring of a Negro-white mating was always different from that of the parents, lighter than the darker parent and darker than the lighter parent. The range of color in second generation (grandchildren of a Negro-white mating) for all tested persons was twice that in the first generation. The children of this crossing (mulatto-mulatto) may be either much darker or much lighter than that of the parents. Penetrance of the Negro skin color trait is not predictable for an individual child, but again, according to Davenport, if the pedigree of the parents can be established, the probable range of color among the children may be given within certain limits. Colored offspring can result from the mating of mixed parents who are phenotypically white. Lewis states, "The conclusive evidence against inheritance of skin color in humans by blending is the occurrence of important differences among children of the same parents found by both Davenport and Barnes. In the light of modern genetics human skin color can be accounted for neither by blending nor by one pair of Mendelian alleles. There are undoubtedly multiple factors, of which at least two pairs (as suggested by Davenport) may be considered of major importance. The combination of multiple factors, with an absence of dominance, is sufficient to account for the known facts, although some of the details are still obscure."

ADMINISTRATION OF IRON

To the Editor:—*In which form is iron best tolerated by the intestines? Does it cause constipation or diarrhea? Are there substances more palatable and simpler to take than hydrochloric acid in the treatment of some anemias?*

M.D., California.

This inquiry was referred to two consultants, whose respective replies follow.—Ed.

Answer.—The most readily assimilable form of iron is ferrous iron, the ferric being less soluble and absorbable. Ascorbic acid will convert ferric iron of food into ferrous iron; consequently it is of value in promoting iron absorption. The rationale behind the use of hydrochloric acid to improve the absorption of food iron is based on the increased solubility of ferric iron in an acid medium. Hydrochloric acid is often used along with specific therapy in the treatment of pernicious anemia, but its effectiveness has not been established. Hydrochloric acid is usually diluted in water and taken through a straw. It is also available in capsule forms, such as glutamic acid hydrochloride and betaine hydrochloride. These solid preparations slowly release hydrochloric acid when in solution. The most widely used preparation of iron is ferrous sulfate, usually administered in 300 mg. doses after meals and on retiring. Colloidal ferric hydroxide is probably less irritating, the average dose being 100 mg. three times a day between meals; however, since iron must be converted to the ferrous form before absorption, any preparation, if effective, is potentially irritating. It is advisable to give small doses during the first few days of therapy to minimize the local irritant action. Moderate doses of iron preparations do not cause constipation or diarrhea except in persons unusually sensitive to the local irritant action.

Answer.—Any ionized form of iron is a protein precipitant and, therefore, irritating to the mucosa of the gastrointestinal tract. Since all available data indicate that only ionized iron is absorbed, it is evident that intestinal irritation by therapeutically effective forms of iron can only be minimized, not avoided altogether. This can be accomplished best by administering the iron after meals, by giving the patient a chance to develop tolerance to iron, and by using doses no larger than are necessary for maximum therapeutic effect. The soluble, simple ferrous salts are most efficiently absorbed and can, consequently, be given in the smallest amount. Many patients, for reasons not understood, can tolerate ferrous gluconate or ferrous glutamate better than ferrous sulfate, although the reverse may also be observed. Tolerance to iron preparations also develops in many persons. For this reason, it is often wise to begin therapy by having the patient take only one tablet after dinner for several days, then one tablet after each of two meals for several days, gradually increasing the dose thereafter, until the full therapeutic dose of three to four tablets (containing roughly 180 to 240 mg. of elemental iron) has been reached. Even if this regimen is followed and several different iron salts are tried, rarely a patient still experiences so much gastrointestinal distress that he finds iron therapy intolerable. In these exceptional cases, it may be necessary to administer iron parenterally, i. e., as saccharated iron oxide. Iron therapy may cause either diarrhea or constipation. The reason for this difference in response to the irritating effect is not known. Hydrochloric acid is of little importance in the treatment of anemias. Its administration does not improve the response to hematinic agents. Occasionally, a patient with achlorhydria may have mild diarrhea or abdominal discomfort, which does improve when hydrochloric acid is given with meals. Many anemia clinics have adopted the policy of treating patients without the use of hydrochloric acid, and then, when the hematological response is complete, the dilute acid is given for one to two months. The patient himself judges whether the added acid has made him feel better; if so, he is permitted to continue its use. There are several commercial preparations of glutamic acid hydrochloride in capsule form that may be used as substitutes for dilute hydrochloric acid.

ANDROGEN THERAPY OF OVARIAN CANCER

To the Editor:—*In discussion of a case of papillary serous cystadenocarcinoma of the ovary by the tumor board of a hospital, the question arose of what the experience has been with the use of testosterone in treatment of this disease. I will appreciate any information you may be able to give on this subject.* *F. R. Moore, M.D., Newport, R. I.*

Answer.—While it would be correct to say that there would be no rationale in androgen therapy for serous papillary cystadenocarcinoma of the ovary or other types of ovarian cancer, such a statement would not be a satisfactory answer, since there is little rationale for the palliative use of the male sex hormones in advanced mammary carcinoma with bony metastases or estrogens in prostatic cancer, although both these plans have yielded excellent results. Scattered efforts at testosterone therapy for both genital tract cancer and ovarian malignant disease have been made, but with no evidence of worthwhile effect. In a recent case of advanced ovarian cancer with peritoneal metastasis observed by this consultant, testosterone had been given in large doses, with extensive masculinization changes resulting, but the patient and her family felt that the growth had been accelerated rather than retarded.

ARSENIC IN THE URINE

To the Editor:—*A man has lost weight, from 160 lb. (72.6 kg.) to 128 lb. (58.1 kg.), over the past two and one-half years. He has no symptoms other than loss of strength and weight, with no desire for food. Results of neurological and physical examinations were normal, except for the lack of muscular strength. X-ray and laboratory examinations were of no aid, except for a test showing fractional amounts of arsenic in the urine. The patient has never received any drug containing arsenic, but tests on the water supply from his local well were positive for arsenic. The water from this well was cut off three years ago, and the deeper well water contains none of this mineral. After one week of dimercaprol (BAL) therapy the urine shows four times the previous amount of arsenic. Is arsenic accumulated in the body from water intake over a period of many years, and may this be accepted as a case of arsenic poison?*

Barnwell R. Baker, M.D., Biltmore, N. C.

Answer.—The description given does not point necessarily to arsenic poisoning, although the loss of weight, strength, and appetite is consonant with the usual features of chronic arsenic poisoning. The quantity of arsenic in the urine and in the water supply would need to be known. Traces of arsenic are always present in urine, and the presence of traces of arsenic in drinking water is not unusual and is without significance. It is observed that the suspected source of arsenic was eliminated three years ago but that arsenic is found in the urine at present. This would make arsenic poisoning from the water supply an unlikely prospect. While arsenic is long retained and slowly eliminated from the body, about 140 days after the last exposure represents the upper limit of retention, and it is scarcely conceivable that it would persist for as long as three years. In the usual low grade chronic arsenic poisoning, skin disturbances dominate the picture, with or without loss of hair and nails. In this instance, it would be desirable to determine the arsenic content of clipped hair and, possibly, finger and toenail trimmings. The determination of arsenic in human tissues or excretions is difficult. Few laboratories have the equipment and experience necessary to provide exact determinations. If, from repeated examinations, harmful levels of arsenic should be demonstrated, this entire matter should be explored fully and a search made for possible exposure sources.

EOSINOPHILS AND CORTISONE

To the Editor:—*What explanation is given for the increase in eosinophils in a patient with sarcoidosis treated by cortisone acetate? Herpes zoster, according to the literature, is helped at times by cortisone or corticotropin. I was in contact with two patients in whom herpes zoster developed while taking cortisone acetate and one in whom it developed while taking corticotropin. What is the explanation for this?*

Joe C. Gilbert, M.D., Lebanon, Pa.

Answer.—No satisfactory explanation can be offered at this time to account for the increased circulating eosinophils after cortisone administration in a patient with sarcoidosis. In the past it was thought that the lack of eosinopenic response indicated insufficient biological action of the hormone; however, it is now known that eosinopenia is not as regularly observed after cortisone administration as after corticotropin administration. If this patient had been treated with corticotropin, a rise in eosinophils could be explained on the basis of allergic hypersensitivity to the corticotropin preparation used. This consultant also has noted on several occasions the occurrence of herpes zoster during cortisone or corticotropin therapy, but in these cases there was surprisingly little associated pain. One might postulate a disturbance in the antibody-virus relationship from these hormones that would allow otherwise neutralized or latent virus to gain the upper hand and produce clinically evident disease. Except for possible amelioration of pain, it is doubtful that these hormones exert any beneficial effect in this disease.

ACTINOMYCOSIS

To the Editor:—*Last week a patient was referred to me with an axillary lesion, which, after a biopsy and culture was shown to be a lesion of actinomycosis. It bled freely when I removed part of it, and I wore no gloves. To stop the bleeding, I had to use several sutures, and I put on gloves at the last. What chance is there that I will contract this disease? What preventive measures should I take? Has any treatment supplanted use of roentgen irradiation and the antibiotics for this disease?* *M.D., Alabama.*

Answer.—There are only a few classic cases in the world literature in which actinomycosis has been known to be transferred accidentally from man to man. It is such a remote possibility in your case that you may rest assured that you did not become infected during your surgical manipulations. The fact that you did not mention having broken areas of skin on your hands is further evidence against such an unlikely possibility. Penicillin and other antibiotics, such as aureomycin and oxytetracycline (Terramycin), are the drugs of choice in the treatment both of local cutaneous manifestations of actinomycosis and systemic involvement. Roentgen irradiation and the use of iodides have been found to be unnecessary adjuncts for successful end results in cases in which the antibiotics are administered.

ROSEOLA INFANTUM

To the Editor:—*I have understood the term "three day measles" to apply to the typical rose rash of infants (roseola infantum), as a disease entity peculiar to infants and not related to either true measles or rubella. I hear the term applied frequently to numerous rashes in adults. Is the occurrence of roseola infantum possible or common in adults?*

M.D., Indiana.

This inquiry was referred to two consultants, whose respective replies follow.—Ed.

Answer.—Roseola infantum is a definite but benign disease of infants and children. It is doubtful that it ever occurs in adults. It is considered a separate and distinct disease from German measles and is known by such names as exanthema subitum and Zahorsky's disease. It has been transmitted from one child to another by means of injection of blood. In roseola infantum, the child has fever for three to five days, and, as the fever is subsiding or within 12 hours after it has subsided, the measles-like rash appears.

Answer.—The term "three day measles" is often applied loosely by the mothers of children who may have had any one of a variety of skin rashes accompanied by mild or no constitutional symptoms. As the name implies, roseola infantum is a disease of infants and young children, principally between the ages of 6 months and 3 years. It has been estimated (Zahorsky) that fully 95% of cases occur in children younger than 2½ years. Few cases have been reported in adults. In large outpatient departments, physicians generally assume a history of "three day measles" to mean rubella.

PREGNANCY IN WOMAN WITH DOUBLE CERVIX

To the Editor:—*A 20-year-old primigravida has two complete cervices, only one of which shows signs of pregnancy. She is nearing the end of the first trimester and has had no bleeding. No bicornate uterus can be palpated. Should this patient be given a chance to deliver her baby vaginally? She has a normal gynecoid pelvis. If she has a single uterine cavity with a double cervical os, should the septum be clipped when effacement is complete and dilatation of the cervix is under way? What are the chances of the uterus' rupturing if it is septate?*

William R. Cotner, M.D., Salina, Kan.

Answer.—Although there may be a lack of fusion of any part of the Mullerian ducts, resulting in any degree of duplication of the uterus and vagina, a double cervix owing to a cervical septum is rare. In all likelihood the septum extends the length of the uterus, or there may be two complete uterine horns. The extent of the defect can be visualized only by hysterosalpingography. Labor can be allowed to proceed naturally. It is not likely that the septum will impede the effacement and dilatation. If the septum is limited to the cervix and does prevent complete dilatation it can be cut. Breech presentation is exceedingly common in women who have uterine anomalies. The baby has been known to straddle a cervical septum, and if this occurs it should be cut early before it is forcibly torn. There is almost no likelihood of uterine rupture because of a septate uterus.

TREATMENT OF PSORIASIS

To the Editor:—*A patient has a severe case of psoriasis, affecting the whole body, except the inside of the arms and the chest. I understand that treatment with Bucky rays has been successful, especially in America. I have been told, however, that in severe cases there is danger of burning internal parts of the body, and that the application of Bucky rays is, therefore, inadvisable. I should be glad if you would let me have your views on this matter.*

M. Lerner, M.D., London, England.

Answer.—The value of Bucky or grenz rays in the treatment of skin diseases is still being debated, and, although some dermatologists advocate treating psoriasis with such rays, it is generally held that destructive rays of any type should not be used for the treatment of a skin disease that, like psoriasis, is apt to recur. Grenz rays, being long wavelength roentgen rays, are absorbed in the epidermis and dermis, so that there is no danger of their burning internal parts, but sequelae, such as those produced by roentgen rays, have been observed in the skin. As a rule it is better to treat severe psoriasis with bland preparations, such as are used for acute dermatitis, since stronger preparations are likely to produce psoriatic exfoliative dermatitis. When the acute stage has subsided, it may be advisable to employ the so-called Goeckerman treatment, in which a combination of coal tar ointment and ultraviolet rays is used. Sometimes autohemotherapy is employed with it. It is a treatment that requires both experience and judgment to be effective.

CLINICAL NEUROSYPHILIS

To the Editor:—*What period of time usually elapses between the appearance of the primary syphilitic lesion and the manifestation of clinical neurosyphilis? Has the number of paretic persons admitted to mental hospitals diminished since the drop in the incidence of syphilis, or is it too early for such a result to be felt?*

J. W. O'Neill, M.D., White Cloud, Mich.

Answer.—This question cannot be answered with regard to clinical neurosyphilis as an entity but only with regard to particular types of neurosyphilis and then only in general terms. Acute syphilitic meningitis is a common accompaniment of secondary syphilis. It may even occur with the primary lesion and before the appearance of secondary symptoms and almost always appears within the first two years of infection. For other clinical types of late neurosyphilis the average incubation period varies. For diffuse meningovascular syphilis, it is probably about 6 to 10 years, for dementia paralytica (general paralysis of the insane) about 12 to 15 years, and for tabes dorsalis about 15 to 20 years. There are, however, exceptions to these statements. Any form of neurosyphilis may, in rare cases, appear within two or three years of infection. On the other hand, the appearance of clinical signs may be delayed for 30, 40, or 50 years. The number of paretic persons admitted to mental hospitals has been dropping steadily since about 1939 (Moore, J. E.: *Am. J. Syph.* **35**:101, 1951).

ENDOMETRIOSIS AND STERILITY

To the Editor:—*What are the recent therapeutic developments in the management of sterility as a result of endometriosis?* *C. H. Denser, M.D., Chatahoochee, Fla.*

Answer.—No new therapy has been discovered that alters much the infertility of women with endometriosis. Some women with endometriosis have pregnancies. There are many factors involved in infertility problems, only one of which is endometriosis. It is not known why patients with this condition seem less fertile than others; only speculation is possible. Estrogens given in adequate amounts (the amount differs according to the patient) relieves the symptoms of endometriosis in most instances. Some believe estrogens have some curative value in the disease. It is likely that the relief of symptoms is the result of the stopping of ovulation by the estrogens. The amounts of estrogens required to accomplish this often are high. There are reports of patients receiving estrogenic substances having conceived. It seems unlikely that patients receiving adequate amounts to relieve the symptoms of endometriosis would become pregnant. Certainly, if amounts high enough to stop ovulation were administered pregnancy could not occur. Surgical treatment seems to help some patients to conceive, but in most cases this is true only early in the disease. The difficult problem is to pick the patients suitable for surgical treatment. In most cases the disease appears more extensive at surgery than was predicted preoperatively, and often the disease so thoroughly involves the pelvic structures that, if properly removed, the remaining organs would be inadequate for pregnancy.

DISINFECTION AGAINST TAPEWORM OVA

To the Editor:—*I would like information on the susceptibility of tapeworm ova, especially of the genus Taenia, to various agents, such as chemicals and heat, that might be used to rid perishable materials of these parasites.*

W. O. Brown, M.D., Scottsbluff, Neb.

Answer.—It is not clear whether by "perishable materials" the inquirer means food that is to be consumed uncooked and whether by "susceptibility of tapeworm ova to chemicals and heat" he means the disinfecting of fecal discharges containing these ova or the rendering of garbage safe for animal food. A summary of information found in a rather exhaustive search follows: Burning or drying is the safest method of disinfecting feces. Boiling will also destroy the ova. Burial is practicable and, if a well is on the premises, should be at least 500 ft. from the well and downhill from it. It should be buried in the upper 2 ft. of soil to protect underground water and to take advantage of natural agencies of purification. The burial spot should not be cultivated for 12 months. For chemical treatment of infected feces, Stiles advises the addition of sufficient sodium hydroxide to make a 3% solution. This will kill hookworm ova in eight to nine days under summer conditions. Taenia eggs with their hard shells will be attacked more slowly. The best method is some septic tank process, as anaerobic fermentation destroys the eggs. Hookworm eggs die in 40 days. Taenia ova require a longer period.

Faust states, "Taenia eggs are very resistant to external conditions. Jepson and Roth of Copenhagen found that they could infect cattle with eggs of T. saginata which had been in excreta for 71 days, free in water for 33 days and free on grass for 159 days. Likewise Newton, Bennett and Figgat (NIH) found that these eggs were apparently 100% viable up to 162 days in activated sludge." Hogs can be fed safely on boiled garbage.

MYOCARDIAL INFARCTION

To the Editor:—*Is the prognosis better in a patient who has had a myocardial infarction and whose electrocardiogram returns to normal than in one whose tracing remains abnormal after clinical recovery, all other factors being equal? Are posterior myocardial infarctions more likely to result in persistent electrocardiographic changes following recovery than are those involving other regions of the ventricular muscle?*

M.D., Pennsylvania.

Answer.—Among patients thought to have had myocardial infarctions whose electrocardiograms later returned to normal, there are likely to be some persons who actually have had some more benign malady, such as pericarditis. It may be suspected, therefore, that prognosis in such a group would be somewhat better than in one that included only persons with persistent QRS changes diagnostic of myocardial destruction. There seem, however, to be no statistical studies to settle the question. Posterior myocardial infarctions are no more likely to show persistent electrocardiographic abnormalities than lesions in other portions of the heart.

SHOULD THE MOTHER NURSE ERYTHROBLASTOTIC BABIES

To the Editor:—*A woman, aged 30, now para 1, gravida 3, who is approaching term, is Rh negative, and her husband is Rh positive. At 34th week of pregnancy, this woman's blood revealed no Rh antibodies. Her first pregnancy was terminated by illegal abortion in the 10th week. The second pregnancy went to term, with spontaneous delivery. The child, now 3, is strong and healthy. Should the mother be permitted to nurse the expected infant? Is it possible for Rh antibodies to be present in the milk of the nursing mother, although not in her blood?* *M.D., New York.*

Answer.—Since in the case described the expectant mother's serum contains no Rh antibodies, the possibility of erythroblastastosis in the infant is excluded (barring sensitization to other blood factors), unless Rh antibodies should appear during the last few weeks of pregnancy. Rh antibodies are never present in the milk when absent from the blood, so that if the mother's serum contains no Rh antibodies, there can be no objection to permitting her to nurse the infant. In fact, experience has shown that there is no harm in permitting erythroblastotic babies of sensitized Rh-negative women to nurse. Apparently, the additional quantity of antibodies that might be ingested and absorbed is so insignificant that it does not aggravate the disease process. In England, erythroblastotic babies are routinely permitted to nurse, since it is considered that the advantages of nursing far outweigh the theoretical dangers of any Rh antibodies the milk may contain.

DEMONSTRATION OF SICKLE CELLS

To the Editor:—*A Negro woman was suspected of having sickle cell anemia. I placed a drop of her blood on a slide, covered it with a coverslip, and sealed it with petroleum jelly. Eight hours later I looked at the slide under the microscope. A white corpuscle was filled with rapidly moving particles, about the size of those you would expect to see in a granulocyte. Is this phenomenon to be expected in sickle cell anemia?* *M.D., Pennsylvania.*

Answer.—The phenomenon of the rapidly moving particles probably is due to Brownian movement of suspended particles in wet preparations and is not of clinical significance. In regard to the sickle cell test, placing a drop of blood on a slide, applying a coverslip, and then sealing with paraffin is an outdated method. It is now well established that sickling is caused by the almost complete insolubility of the reduced pathological sickle cell hemoglobin within the cells. Sickling will only occur if this pathological pigment is sufficiently deoxygenated. Reduction of hemoglobin without damage to the cell is best achieved by adding two drops of a freshly prepared 2% solution of sodium metabisulfite ($Na_2S_2O_5$) to one drop of blood and then covering the mixture with a coverslip. After 5 to 15 minutes the sickled cells are readily demonstrable.

ANTIBIOTICS

To the Editor:—*At a recent postgraduate course, the lecturer stated that only penicillin and streptomycin were bactericidal and that all the other antibiotics, such as aureomycin and oxytetracycline (Terramycin), and also the sulfonamides were bacteriostatic. Please comment on this subject.* *M.D., New Jersey.*

Answer.—All antibiotics and commonly used sulfonamides are bactericidal in vitro against certain strains of micro-organisms, if present in high enough concentrations. What the lecturer meant was that in certain types of infections, produced by susceptible strains of organisms, penicillin or streptomycin may be bactericidal in the concentrations of the antibiotic obtained in the blood of the patient, by standard methods of therapy. As a rule of thumb, it is better for the physician to assume that the action of the antibiotic he is employing will be bacteriostatic. This is the effect that will be obtained in the majority of patients.

PAIN IN ARM ASSOCIATED WITH BOWEL MOVEMENTS

To the Editor:—*I have seen a few patients who have a neuralgic type of pain in the left arm while having a bowel movement. I saw two patients with anal inflammatory lesions (fissure and cryptitis) complaining mildly of the same pain. Is this a definite reflex entity or just a happenstance?*

Glenn A. Hopkins, M.D., Guymon, Okla.

Answer.—There are no reflex connections that could account for neuralgic pain in the arm occurring in association with a bowel movement or with an anal lesion. Straining to move the bowels may aggravate or precipitate pain in the arm from an intraspinal lesion, such as a spinal cord tumor or a herniated cervical intervertebral disc. Whether such an intraspinal lesion is present in these patients would be impossible to say without a more complete examination.

PRESENT DAY TREATMENT OF SUBACUTE BACTERIAL ENDOCARDITIS

THE MINOT LECTURE

Chester S. Keefer, M.D., Boston

In the first Minot lecture, Dr. Castle[1] reviewed and commented on the contributions of Dr. Minot to the field of experimental medicine. In the second Minot lecture, Dr. Sturgis[2] summed up the information concerning a subject that was of lifelong interest to Dr. Minot, namely, leukemia. It was through a patient with a disorder of the blood coagulating mechanism, purpura hemorrhagica, that I met Dr. Minot for the first time. He visited Baltimore late in the autumn of 1923, and my colleague Dr. A. R. Felty and I had the opportunity of discussing with him the illness of the patient who, although she had had acute purpura hemorrhagica from which she recovered spontaneously, had remained well for several months without relapse. It was at that time that I learned of Dr. Minot's deep interest in the broad field of hematology and scientific medicine. Later, as a member of his staff at the Thorndike Memorial Laboratory, I came to appreciate Dr. Minot's contributions to experimental medicine and therapeutics and his example of university medical ideals.

The fact that this section is called experimental medicine and therapeutics is a conspicuous recognition of the fact that the practice of medicine is founded on the experimental method. There is no denying that it is from experiment and a search for the truth that scientific advances are made. Also, no thoughtful person will deny that medical progress during the first half of this century has stemmed primarily from the accumulation of scientific knowledge and its application to the prevention of disease and to the care of the sick through improved medical education and public health practice. Certainly, the central core of a better understanding of the sick stems from the advancement of knowledge and its transmission by our university medical schools. Dr. Minot was a physician who was educated in the basic medical sciences and one who practiced the university medical educational ideal. Through experiment, through the furtherance of knowledge, and through its translation to patients he added much. Dr. Minot learned how to apply the facts of fundamental science that were of practical benefit to the sick. For these reasons, I want to discuss a disease that serves as an example of what can be learned through experimental medicine over a period of 100 years to lead to a partial solution to the problem. I refer to bacterial endocarditis.

Within recent years, it has been found that in many cases bacterial endocarditis, like many other bacterial infections, can be treated successfully. This is especially true of that form of bacterial endocarditis commonly known as subacute bacterial endocarditis caused by Streptococcus viridans or one of the related nonhemolytic streptococci.

RESULTS BEFORE ADEQUATE THERAPY

Before the active therapeutic age, patients with bacterial endocarditis fell into four major groups: first, those in whom the disease was active, with or without bacteremia, and in whom death occurred within 4 to 18 months after the onset of symptoms and signs of infection. This group comprised about 97% of all cases. Second, there was a small group of patients who recovered from the active infection of the heart valves but who died subsequently from the sequellae of the infection, that is, from heart failure, chronic nephritis, or embolism. These patients usually died within one to three years after signs of active infection disappeared. Third, there was a small group of patients who recovered from the infection and remained well for many years without symptoms. Fourth, there was a group of patients in whom there was an arrest of the infection but in whom signs of either recurrence or reinfection developed at a later date; these died of active infection.

These four groups are seen today, but their distribution is quite different. More and more patients recover from the acute infection, but other problems remain. In order to develop better methods of treatment and to

improve results, it is essential that the effect of the infection on the heart valves and the reaction of the valves to the injury be understood.

COURSE

It is now widely accepted that the primary insult to the endocardium in all forms of endocarditis, whether bacterial or nonbacterial, is the formation of a thrombus consisting of platelets and fibrin. These thrombi are located along the main line of closure of the valves, oftenest the mitral and aortic and least often the tricuspid and pulmonary valves. The disposition of these thrombi depends on the nature of the injury. If the thrombi are free of bacteria or if they contain bacteria that are promptly killed then organization proceeds, healing takes place, and a scar remains. There may be no valvular insufficiency, or the scar that persists may lead to either valvular insufficiency or obstruction. If there are bacteria in the thrombi and if they are not killed promptly, they grow rapidly and, in many instances, infect the blood. These infected thrombi or vegetations are larger than the nonbacterial forms. They are soft and crumble easily. As a result of the growth of bacteria and their spread to surrounding areas, the thrombi may become massive and may occlude the valvular orifice, or there may be rapid destruction of the valve leaflets with insufficiency; the emboli may be swept into the circulation. From the line of closure, the vegetations grow to the edge of the valve, down into the sinus of Valsalva, along the chordae tendineae, or along the auricular wall, or they extend from the base of the valve into the myocardium to produce a burrowing abscess or perforation of the septum. Thus, this infection that begins as a valvular thrombosis may cause obstruction or destruction of valves with changing heart murmurs and hemodynamics or rupture of chordae tendineae, with the changing heart sounds and murmurs and attacks of pulmonary edema. There may be formation of mycotic aneurysms of the valves or of the sinus of Valsalva, with occasional rupture or leakage into the pericardium and formation of pericarditis; perforation of the septum, with the clinical signs of heart block; an abscess of the heart wall, with rupture; an occlusion of the coronary artery by a thrombus; or, finally multiple emboli to various organs. Thus, the course of this infection may be followed if some of the ways in which the infection behaves are understood.

In the cases of so-called subacute bacterial endocarditis caused by Str. viridans, the vegetations are pinkish, greenish, or yellowish. They rarely cause ulceration and massive destruction of the valves, and the thrombi, or vegetations, are smaller than those commonly seen when the infecting organism is Staphylococcus aureus, pneumococcus, or gonococcus. Auricular vegetations and others involving the chordae tendineae are common, and bacterial emboli are scattered in great numbers to the various organs including the brain, the kidney, and the small blood vessels.

The blood is infected with these bacteria in a majority of the cases, but there may be a bacteria-free stage in which the vegetations show signs of healing or in which they heal completely leaving a scarred, thickened, shortened valve that is draped with large calcified masses.

CHARACTER OF THE THROMBI

The thrombi have been described many times, but Moore [3] examined the vegetations from the heart valves of persons dying from subacute bacterial endocarditis who have not been treated with penicillin. He compared his findings with those from persons who were treated unsuccessfully with penicillin. In short, a vegetation consists of three layers: a central necrotic core of relatively acellular, fibrillar debris and two layers of bacterial colonies surrounding this central core, both of these layers are covered by a delicate fibrillary, acellular material resembling fibrin and platelets. It is apparently difficult for leukocytes to penetrate the barrier of fibrin and platelets. There is also some indirect evidence that anti-infective agents have difficulty in diffusing through this wall.

If the patient lives long enough, there are signs of healing of these vegetations. Healing is characterized by calcification of the vegetations and organization and distortion of the valve. According to Moore, the healing of a thrombus is characterized by fibrosis, hyalinization and calcification of the central necrotic mass, and covering of the surface with endothelium. The effect of penicillin is to reduce or kill the total number of bacteria and to promote the healing of vegetations, since the patients who receive penicillin but who die show more advanced healing than those who are not treated.

The factors that need more study and better understanding are those that promote healing. There are many cases on record in which healing was not completed for many months after the cessation of treatment. There are many reports on "clinically" cured patients who died from other causes but from whom, at necropsy, live organisms were cultured from the heart valves. It has been stated by Cates and Christie [4] that, after death, organisms may be cultured from 30% of the patients in whom the usual clinical criteria for the control of infection were established. Unfortunately, there are no absolute methods of determining that healing has taken place other than through careful study and follow-up of patients.

RESISTANCE TO CHEMOTHERAPY

It is plain that one problem is learning more about the factors that protect the organisms in the vegetations from the full impact of chemotherapy. Attempts have been made to gather and to accumulate more information about the problem of the penicillin penetration of the fibrin barrier in the vegetations so that all organisms are killed. It is well known that micro-organisms can grow in fibrin, and it is well established that penicillin can diffuse into fibrin clots. Also, it has been demonstrated experimentally in animals and in the test tube that micro-organisms growing in fibrin clots can be killed if the concentration of penicillin is adequate. These problems have been studied with great thoroughness by Weinstein and his associates.[5]

[4] Cates, J. E., and Christie, R. V.: Subacute Bacterial Endocarditis: Review of 442 Patients Treated in 14 Centres Appointed by Penicillin Trials Committee of National Research Council, Quart. J. Med. **20**: 93, 1951.

[5] Weinstein, L.; Daikos, Y., and Perrin, J. S.: Studies on the Relationship of Tissue Fluid and Blood Levels of Penicillin, J. Lab. & Clin. Med. **38**: 712, 1951. Personal and unpublished observations.

Weinstein and associates found that penicillin diffuses into fibrin clots slowly so that at least two hours are required for the concentration of penicillin in the clot to reach the same concentration as in the surrounding fluid. When a fibrin clot is implanted subcutaneously and the animal is treated intramuscularly with penicillin, the antibiotic diffuses into the clot and persists there for a longer period than in the surrounding tissue fluids. There is also a direct relationship between the quantity of penicillin administered intramuscularly and the quantity of penicillin in the fibrin clots.

If fibrin clots are infected with various organisms (pneumococcus, hemolytic Streptococcus, and Staph. and Str. viridans) all of the same order of in vitro sensitivity and then planted subcutaneously and the animal treated with a single injection of penicillin, it has been shown that Str. viridans behaves differently from the other three organisms. It was found that sensitive pneumococci and staphylococci were eliminated within 8 hours, that hemolytic streptococci were destroyed within 48 hours, but that Str. viridans decreased over a period of 12 hours and then continued to grow out. These experiments suggest that even penicillin sensitive strains of Str. viridans can survive in fibrin clots after exposure to concentrations of penicillin capable of destroying other organisms. These experiments assist the understanding of some of the features seen in patients; that is, intermittent or discontinuance therapy may be effective if the plasma concentrations of penicillin are high enough to penetrate the fibrin barrier and if the concentration of penicillin is maintained in the area for a sufficient period of time to provide maximum killing. They do not explain the reason it is more difficult to kill sensitive Str. viridans in a fibrin clot than other equally sensitive organisms.

These then are some of the problems in planning treatment. It is plain that the main goals of treatment are to destroy all of the micro-organisms in the vegetations and to prevent a recurrence of infection. To achieve these objectives, it is desirable to know how sensitive the infecting organism is to a bactericidal agent and to use these agents in sufficient quantity and for a sufficient period of time to penetrate the fibrin barrier and to kill all of the organisms.

USE OF ANTIBIOTICS

It has been shown that at least 90% of all strains of Str. viridans are inhibited by concentrations of penicillin of 0.01 to 1 unit per milliliter and that the treatment of these strains is usually successful when adequate penicillin is given. If the organism is resistant to one or more units of penicillin then the results of treatment with penicillin alone are not wholly satisfactory. Cases in which this occurs frequently require combined antibiotic therapy or penicillin and renal tubular blocking agents such as probenecid (Benemid).

Selection of Antibiotics.—It is generally agreed that penicillin is the antibiotic of choice for the treatment of all sensitive strains of nonhemolytic streptococci and Str. viridans and that penicillin and streptomycin should be used in combination in all cases of enterococcic endocarditis.[6]

Occasionally, other combinations of antibiotics, such as penicillin and chloramphenicol or penicillin and bacitracin, are useful in the treatment of resistant infections.[7] These resistant organisms can be tested for their sensitivity in vitro in order to obtain a guide for selection of combined therapy.

Forms.—The two most widely used forms of penicillin for the treatment of subacute bacterial endocarditis are aqueous crystalline potassium penicillin G and procaine penicillin G. The first form may be combined with probenecid if high plasma concentrations are desirable and necessary. Procaine penicillin G has been used with success when fewer daily injections are needed.

Dosage Schedules.—Many different dosage schedules have been recommended, and, in spite of the variation of plan, two points stand out. First, the total duration of treatment is as important as the total daily dose of antibiotic. It has been suggested on the basis of study of many patients that the minimum daily dose of penicillin should be at least 2 million units and that treatment should be continued for a minimum period of four to six weeks. Naturally, the daily dosage must be gaged by the patient's response to treatment. There has been a trend recently to use larger doses of penicillin (10 million units) combined with streptomycin (1 to 28 mg.) daily for two weeks or large doses of penicillin alone for only two weeks.[8] Favorable results have been reported. When short-term treatment is employed, the patients should be watched very carefully for signs of relapse or recurrence of infection, since bacteriological relapse often occurs before clinical relapse. Relapses are most frequent during the first four weeks after treatment is discontinued. The final decision concerning dosage must rest with the clinical course of the patient, and new experience with experimental dosage schedules continues to demand attention.

SUMMARY

The over-all results of present treatment can be summed up as follows. 1. Some patients recover from the infection and remain well and asymptomatic for a period of years. This group makes up 60 to 70% of cases. 2. Some recover from the signs of infection and die later of heart failure, uremia, or cerebral embolism. This group accounts for a steady death rate, after the first six months, possibly equal to the normal death rate in patients with valvular heart disease. 3. Patients die during treatment, usually within the first two months, with signs of active infection, heart failure, cerebral embolism, or hemorrhage. This group comprises about 10 to 30% of all cases. 4. Some patients recover from an initial infection only to have reinfection occur at a later date. This group is very small, about 2%.

CONCLUSIONS

We have come a long way on the path to victory or in the war against bacterial endocarditis, but now is the time to consolidate our gains, to assess the present position, and to plan for the future, because there is still much to be accomplished.

---

What have we gained? We have prolonged the life expectancy of patients with rheumatic heart disease and with congenital heart disease in whom subacute bacterial endocarditis has developed. Moreover, many who have recovered have remained well and are able to be active at least over a period of years. To assure complete victory, we must achieve, first, the prevention of rheumatic heart disease, the complete prevention of hemolytic Streptococcus infection. Next, we must prevent congenital heart disease. This is a task for geneticists and teratologists that needs the attention of all university medical scientists. Third, we must prevent infection, especially oral sepsis and other local infections that commonly invade the circulation and localize on the heart valves when the local defense mechanism is ruptured or penetrated. This objective may be reached by further study of problems of infection.

I believe that these goals can be reached only through the pursuit and accumulation of scientific knowledge through the ideals of experimental medicine and therapeutics, namely, the advancement and transmission of knowledge. Through experimental medicine and therapeutics, advances will continue on a broad front. The example set by Dr. Minot is one that is fully recognized.

RESULTS OF INTENSIVE (NARCOSIS) AND STANDARD MEDICAL TREATMENT OF EPILEPSY

Tracy J. Putnam, M.D.
and
Sanford F. Rothenberg, M.D., Beverly Hills, Calif.

The years 1935 to 1939 at the neurological unit of the Boston City Hospital witnessed the beginning of a revolution in the understanding and control of epilepsy. In this clinic, then under the supervision of one of us (T. J. P.), electroencephalography for the first time became a routine clinical service, and its special value in the field of convulsive disorders was demonstrated.[1] The resultant knowledge was utilized to study the effects of various drugs and physiological states on cerebral dysrhythmia.[2] Against this background, one of us (T. J. P.) formulated the conception of a series of specific anticonvulsant drugs, suggested a molecular configuration that has since proved highly successful in several variations, and set up a simple, reliable method of testing the effects of such drugs in animals.[3] The significance of these suggestions and of the theoretical considerations and administrative manipulations that later led to the demonstration of the usefulness of glutamic acid in cases of petit mal [4] and related disorders [5] lies in the fact that they grew out of fundamental neurophysiological considerations and experience. This is a little different from the routine study of chemical series by pharmacologists utilizing established methods of testing,[6] or the routine clinical testing of the products of such investigations,[7] valuable as both may be.

Clinical trial of the new series of drugs was left largely in the hands of Dr. Merritt,[8] who was in charge of the epilepsy clinic in the outpatient department. He meticulously weighed the results and has since continued his interest in similar investigations.[7m] At that time, the foundation of the standard treatment was laid, namely, the principle of starting treatment in new patients with well-known drugs, increasing the dose to the tolerance level, and then gradually shifting to other drugs, which eventually are given in maximal tolerated doses, if relief is not obtained earlier.[7d] Similar studies have been carried out by other members of the original team, now scattered, and their colleagues, with signal success.[9] The recently developed method of rapid determination of optimum medication [10] is clearly an outgrowth of this former association.

The term "standard treatment" apparently was first used by Price and Otto,[7i] without definition. We take it to mean a flexible scheme of treatment in which changes from one drug to another are made until the most effective drug or combination of drugs is found and in which other effective modes of treatment are used, simultaneously or in series, when needed. The chief practical problem is no longer that of attempting to show that anticonvulsant drugs need not be sedatives. This has been done, and the preparation of new variants must be left chiefly in the hands of chemists and pharmacologists. The clinical problems now consist of making a selection among the various drugs and other methods available and searching for new techniques of their application. Methods of selection have been considered in a recent paper [10b]; this paper deals chiefly with methods of use and results.

Although the principles of the standard treatment so far have never been clearly delineated, they have been followed with varying faithfulness in various clinics [11] and, perhaps as a result, with varying degrees of success, as may be seen in the table. (The grading used in the table is that used by Penfield and Steelman.[12]) A few patients in whom the more vigorous and flexible medical treatments failed (grades 0 or 1 response) are suitable candidates for various surgical procedures (chiefly excision of scars or other abnormalities [13]). The remaining unrelieved patients are often dismissed as being untreatable and may have to be institutionalized. It was in the hope of salvaging some of these latter patients that the intensive, or narcosis, treatment was conceived and

first used. Before describing the method and its results, we should like to record the rules governing use of the standard medical treatment and our results with it, to demonstrate that we have not resorted to a drastic, possibly dangerous, new procedure lightly or inadvisedly.

STANDARD MEDICAL TREATMENT

The following principles of selection of drugs and general conduct of treatment, which we have followed as rigidly and thoroughly as possible for all patients coming into our care, are condensed from a recent paper [10b]:

1. Relatively well-known and nontoxic drugs are preferred to dangerous or untried ones. From the standpoint of serious, permanent toxic effects, diphenylhydantoin (Phenytoin, Dilantin) is probably the safest drug, with phenobarbital and bromides in close competition. Glutamic acid appears entirely safe, but may cause gastric irritation, is often disagreeable or even intolerable to the patient, and is of value in only a small proportion of cases. A significantly high proportion of alarming or fatal reactions have been reported from the use of Mesantoin (3-methyl-5,5-phenylethyl hydantoin), trimethadione, paramethadione, phethenylate (Thiantoin), and phenacemide, the risk increasing about in the order the drugs are listed. Close laboratory and clinical supervision is essential when these latter drugs or bromides are used, and, as Abbott and Schwab [15] have pointed out, this materially increases the patient's economic burden.

2. Treatment should always be started with the most familiar, well-tested, and reliable drug, and newer, less well-known drugs should be added or substituted only for clear cause. Formerly, phenobarbital was the accepted standard,[7d] but the steady success and now obviously low toxicity of diphenylhydantoin has caused us to consider it as first choice, regardless of the clinical type of seizure. The initial dose is usually 0.2 gm. daily and it is gradually increased at the rate of 0.1 gm. weekly. Diphenylhydantoin in oil should be used when gastric irritation results from the use of the sodium salt. It is also useful for infants, for whom the drug has to be mixed with food. Diphenylhydantoin is sometimes effective even when its use produces no effect on the electroencephalogram during a rapid determination. Phenobarbital is our standard second choice. In many of our patients, new drugs undergoing clinical trial have been used after the commercially available ones have proved ineffective. So far, little has been accomplished with such drugs.

3. The dose of each new medicament should be increased gradually until symptoms of overdosage are produced, and then it should be reduced slightly. From our experience, it is wholly clear with respect to diphenylhydantoin and reasonably clear with respect to other drugs used that individual needs and tolerances vary widely and cannot be predicted. In many, perhaps in most, patients the effective dose is close to the toxic dose.

Hypertrophy of the gums, which occasionally occurs as a toxic effect of diphenylhydantoin therapy, can almost always be controlled by vigorous massage.[16] The administration of ascorbic acid may also be tried. Amphetamine is often useful in combating drowsiness caused chiefly by phenobarbital. Toxic rashes and leukopenia in two patients in this series apparently have been controlled by the use of cortisone. Unless a medicament under trial is clearly toxic or useless, its use should be continued until the next drug to be evaluated is being given in reasonable doses.

5. The method of increasing the dose of each drug gradually to the tolerance level, adding new ones to the regimen if the ones previously used are inadequate, and gradually discarding those obviously ineffective or deleterious should be continued until the seizures are controlled or until use of all the available drugs has been tried. About three months are required for thorough trial of each new drug or combination of drugs. This period of experimentation, which is often tedious and sometimes almost intolerable, may often be shortened by use of the method of rapid determination of optimum medication,[10b] which has obvious disadvantages also.

6. The use of phenobarbital and probably, also, of Mesantoin, usually should be avoided if spike and dome or "psychomotor" complexes are present in the electroencephalogram or if definite, typical petit mal, dullness, or psychomotor manifestations are present. Phenobarbital, especially, sometimes seems to convert typical petit mal attacks into psychomotor outbursts, suppressing also the "spike" in the electroencephalogram. The use of trimethadione, paramethadione, or glutamic acid should be avoided except in cases in which some or all of these manifestations are present. Use of one of these latter drugs usually should be accompanied by a maximal tolerance dose of one of the hydantoins (diphenylhydantoin or Mesantoin).

7. Diphenylhydantoin, when the dosage is pushed to the tolerance level, is the drug of choice in patients in whom psychomotor phenomena or periodic dullness [10b] are predominant. Glutamic acid, trimethadione, paramethadione, and phenacemide are preferred next, in that order. Amphetamine may be tried. Vigorous exercise should be required of the patient.

8. Patients should be instructed to report the occurrence of one or a few seizures, and the dose of the drug they are using ordinarily should then be increased, or a new agent should be added. In the long run, especially in growing children, some drug tolerance may gradually develop, and the tolerance dose should be readjusted every year or when symptoms recur.

9. The use of adjuvant therapy, such as exercise, avoidance of strain and fatigue and deleterious activities, and simple psychotherapy, is almost always advisable. Extreme moderation in the use of alcohol must be insisted on.

10. Surgical measures should be considered only when adequate standard medical treatment, as defined, and, perhaps, a trial of intensive treatment, as described in this paper, have failed.[12] Similar medical measures usually have to be carried out after cortical extirpation [17] and only sometimes are more effective afterward than they were before.

These rules are easily followed initially, but the program is often difficult to carry through. Often the first drug tried, usually diphenylhydantoin, is successful at once or as soon as the maximal tolerance dose has been found. In about 26% of our 75 patients, however, the period of trial and error became so prolonged and costly to the patient that a rapid determination of optimum medication was undertaken and led to its establishment immediately or shortly in 6 patients.

RESULTS OF STANDARD TREATMENT

The patients used for evaluation of the strict standard treatment were unselected, except that the majority had been unsuccessfully treated elsewhere. They consisted of 33 patients seen in the outpatient clinic of the Cedars of Lebanon Hospital and 52 seen in private practice over a five year period (1947 to 1951, inclusive). Although relatively few children are included in this series, on the whole, treatment has been more successful among the children than among the adults. Patients in whom treatment was prematurely stopped for reasons unrelated to the disease, those treated for less than one year, and those in whom the seizures were obviously due to some gross lesion requiring surgical treatment were excluded. Otherwise, no special attempt was made to classify the patients into cryptogenic and symptomatic groups, because in our experience, as in that of Yahr and co-workers,[7m] such attempts at classification do not seem greatly to affect therapeutic results. Owing to the length of time required to complete the many steps of the standard treatment in difficult cases, a large group remains in whom treatment is not yet finished. The proportion of such incompletely treated patients is especially high in the clinic.

The results obtained with the method described are recorded in the table, where they are compared with other series reported in the literature and with the recovery rate in untreated series of patients. Trousseau gives this latter rate as 13%[18] and Herpin as high as 50%.[19] It probably is significant that prior to the advent of diphenylhydantoin, statistics showing the proportion of patients maintained seizure-free are extremely rare.

As many authors have noted, conscientious evaluation of results is difficult to attain. We have adopted the simple classification reported by Penfield and Steelman,[12] into which most reports may be fitted with reasonable accuracy. These authors group results as follows: grade 0, failure; grade 1, 25% improvement; grade 2, 50% improvement; grade 3, 75% improvement; and grade 4, 100% improvement. This rating is designed for a study of the results of surgical treatment, which was considered concluded at the time the patient left the hospital. The designation of such a definite end-point is not possible in assessing the results of medical treatment, including the intensive form, the full results of which may not be apparent until weeks or months after the period of narcosis has ended. We have, therefore, perhaps arbitrarily, taken the position that the standard treatment is completed only after the patient is either relieved of his seizures for a year or has been given a thorough trial of all or almost all forms of medication likely to help him. In some cases, this trial periods was accelerated by the use of the method of rapid determination,[10b] and certain reasonably obvious omissions were made; for example, patients who had grand mal alone were seldom given a trial course of trimethadione, paramethadione, or glutamic acid. It has been our policy to postpone the use of the drastic and expensive intensive treatment until the full course of the standard treatment has been given.

The criticism may be made, with some justification, that this group of "completely treated" patients contains an unduly large proportion of patients likely to be relieved by almost any reasonable form of treatment. It is true that control of the seizures is the commonest reason for transferring a patient out of the "incompletely treated" category. During the five year period in which most of this data was being collected and 75 patients had been established on a level of medication we considered optimum, with or without the intensive treatment in patients not seizure-free, we had also begun treatment of 25 others, which we do not yet consider completed, since the use of several drugs remains to be tried in each. Seventeen (68%) of these latter patients have now attained grade 3 improvement, that is, they are free of grand mal seizures or are able to work.

Of the 75 patients in our "completed" series, 58 are taking diphenylhydantoin in doses up to 0.6 gm. daily, 12 are taking phenobarbital, 12 Mesantoin, 7 trimethadione, 3 paramethadione, 2 each phethenylate, glutamic acid, and AC 268 (5-isopropoxymethyl, 5-phenyl hydantoin [Parke-Davis]) and 1 each phenacemide, Hibicon (3-chloro-N-benzylpropionamide), and mephobarbital (Mebaral). The various combinations of these drugs empirically derived are too complicated to report. Milontin (N-methyl-α-phenylsuccinimide), Nuvarone (3-methyl-5-phenylhydantoin), and several other drugs still in the experimental stage of use have been given trials but have not seemed as valuable as those just listed.

Ives,[11b] Peterman,[7j] and others refer to phenobarbital as the least toxic anticonvulsant drug available. We have been unable to corroborate this in our series. In our experience, phenobarbital is always toxic in doses over about 0.1 gm., producing a drowsiness or depression that seriously impairs the patient's work ability and social adjustment. Further, deaths from the suicidal use of phenobarbital [20] far outnumber deaths questionably attributable to the use of diphenylhydantoin.

INTENSIVE (NARCOSIS) TREATMENT

Since a certain proportion of failures occurs with every type of treatment of epilepsy, no matter how intensive or flexible it may be, the search for better forms of treatment must continue. The idea that some relatively brief, intensive medical treatment may be found has many roots, stretching far back into the past.

It has long been known that surgical procedures of many types may be followed by long periods of relief from seizures. The series of 62 cases of craniotomy, with 42 "cures," collected by Billings [21] well exemplifies this. Many physicians can remember when it was considered good for epileptics "to have their colons reduced to semicolons," as Dr. Frederick Collins expressed it, and the statistical results as reported were encouraging. Relatively brief periods of starvation or longer periods of ketosis are sometimes effective in bringing about a remission of seizures, but either procedure is disagreeable to the waking patient. Possibly, a short period of ketosis may be combined with a prolonged period of narcosis, simulating anesthesia. One of us (T. J. P.) used phenobarbital for this purpose in a few patients about 10 years ago, but without much success. According to Lennox,[22] this same idea was put into practice by Cooter more recently. One-third of his patients are reported to have remained seizure-free after 10 days of such treatment, but it was abandoned after several serious mishaps. A case reported in 1942 seemed significant in several respects: "An interesting case was described by Dr. E. S. Montgomery of Tarentum, Pennsylvania, who wrote in February, 1942, of a patient with pneumonia who was given at each time of sulfapyridine medication a capsule of dilantin [diphenylhydantoin] sodium making a total of 3.2 gm. in fifty hours at which time the patient became comatose with a pulse rate of 42 per minute. The pupils were unequally dilated, the tongue and buccal membranes were dry, the blood pressure 60/20-mm. Hg and there were no tendon reflexes. Fifty hours after the overdosage was discovered the patient asked for water and recovery from this point was uneventful." [23] Dr. Montgomery writes us that this patient is still in good health and free of seizures, and he adds, "I have treated 9 additional cases with large doses of dilantin sodium and 7 of these patients have been symptom free for periods beyond six years. Some of the 9 patients were given doses of dilantin in excess of 4.0 gm. daily for varying periods of 3 to 10 days."

Because of these experiences, we decided to determine the effect of prolonged narcosis, produced chiefly by diphenylhydantoin, combined with the production of ketosis, administration of glutamic acid, and frequent inhalations of carbon dioxide, which are known to abolish slow wave activity in most patients.[2b] The following case reports illustrate the nature of some of the problems that led us to feel justified in taking such a drastic step.

REPORT OF CASES

CASE 1.—A 33-year-old man, referred to us by Dr. Daniel Castile of Riverside, Calif., had sustained a skull fracture and cerebral concussion 11 years prior to his first visit July 28, 1947. At age 26 grand mal and minor seizures had developed. The grand mal seizures were often preceded by an aura of numbness and tingling of the left hand. They occurred one to five times per week without medication; however, when the patient received maximum doses of diphenylhydantoin, they occurred one to two times a month. In 1946, the patient had bilateral burr holes placed for removal of a subdural hematoma that occurred after a head injury sustained during a grand mal seizure. In the previous three years, the patient had had difficulty with his gait.

Neurological examination revealed the following positive findings: Bilateral burr holes were palpable in the frontoparietal and temporal areas. There was mild left lower facial paresis, and mild bilateral vertical nystagmus. The temporal margin of the left optic disc was indistinct, and the temporal half of the disc was bluish-white, especially in the superior temporal quadrant. The reflexes were hyperactive throughout, and Babinski and Hoffmann signs were elicited bilaterally. The abdominal reflexes were absent, but the cremasteric reflexes were intact. The patient had an unsteady, broad-based gait and a slightly positive Romberg sign. Dr. N. A. Bercel's interpretation of electroencephalograms was as follows: "A marked dysrhythmic record at 100 μv maximum. Both frontomotor areas are more involved than the rest of the cortex. There is only a faint suggestion that the left one is the more active side." Other routine laboratory examinations showed nothing of apparent importance.

The patient had been given many different drugs in large doses, including bromides, phenobarbital, and diphenylhydantoin. After some experimentation, it appeared that the following combination of drugs was most effective for him: diphenylhydantoin 0.3 gm., mephobarbital 0.3 gm., Mesantoin 0.4 gm., and trimethadione 1 gm. daily. These amounts represented approximate subtoxic doses of each. The patient felt slightly unsteady but had an average of only one attack daily.

Since the patient was still incapacitated, he was admitted to the Cedars of Lebanon Hospital Dec. 3, 1947, for further study. A ventriculogram was made to make certain that no hematoma or gross scar was present. This showed five old trephine openings, as expected, and a moderate symmetrical dilation of the ventricles. Electroencephalograms were made and showed dysrhythmia, with abnormalities in the anterior third of both hemispheres. Inhalation of a carbon dioxide mixture promptly temporarily wiped out the abnormalities.

As no other means of treatment seemed available intensive treatment was considered. Its theoretical background was explained to the patient and his relatives, and the procedure was accepted by them. Beginning Dec. 5, 1947, the patient was given 0.9 gm. of diphenylhydantoin by mouth daily, with phenobarbital as needed to keep him drowsy, and inhalations of 5% carbon dioxide with 95% oxygen for five minutes every two hours. Special nurses were in attendance day and night. The patient was kept so drowsy that he lay quietly and did not talk but would sometimes arouse between doses and take nourishment and fluids or attend to bodily functions. After the second day, intravenous injections of glucose were required to prevent dehydration. The anticonvulsant medication was withdrawn Dec. 8, and the patient became sufficiently alert the following day to attend to his own needs, so the special nurses were dismissed. On Dec. 10, he was given two doses of 15 mg. of amphetamine to overcome drowsiness and was permitted to return home. Prescribed medication for home use consisted of diphenylhydantoin 0.3 gm., mephobarbital 0.3 gm., Mesantoin 0.4 gm., and trimethadione 1 gm. daily, which was the same amount the patient had taken before his operation.

The patient had no more seizures and returned to his occupation as a rancher. This period of improvement lasted 10 months, when he again began to have minor seizures, which he attributed to a severe emotional disappointment. By this time, we had had more experience with the intensive treatment, and we recommended that it be repeated in a more drastic form. Accordingly, on Sept. 22, 1948, similar precautions being taken, the patient was again given 0.9 gm. of diphenylhydantoin daily, supplemented by 0.2 gm. of phenobarbital every two hours or as needed to keep him drowsy, and a carbon dioxide-oxygen mixture as before. He became deeply narcotized by Sept. 24, when evidences of mild bronchopneumonia accompanied by a diffuse erythema developed. Diphenylhydantoin and phenobarbital administration was, therefore, discontinued. The patient continued to sleep deeply, still receiving inhalations of the carbon dioxide-oxygen mixture. His respiration became shallow, and the periods of administration of carbon dioxide were lengthened. A slight fever and rales in both sides of the chest developed. Antibiotics were given. The patient had several mild seizures daily from Oct. 6 to 12. He was, therefore, given the maintenance medication he had been taking on admission. Because the seizures continued, on Oct. 14 narcosis was induced again with the same combination of drugs previously given. This was continued through Oct. 19, this time without complication. The patient was awake and able to take care of himself on Oct. 23 and was discharged Oct. 26, after which he began taking the same medicaments in the same dosage that he had been taking on admission, plus 1 gm. of phenacemide daily. He has been followed closely since that time and has had no major seizures. Occasionally he had tingling of the fingers of the left hand when dropping off to sleep, but even this has disappeared in the last year. The left arm has grown weaker and more spastic, however. The phenacemide was omitted from his list of medicaments in 1949, and the dose of Mesantoin was decreased in 1951. He has been working steadily and has been granted a driver's license.

Case 2.—A boy was first referred to us by Dr. Norman Reider of San Francisco July 27, 1949, when he was 17 years old. He had had his first attack at age 12. He would walk around in a circle and then fall unconscious to the floor. The frequency of these attacks gradually increased, until they occurred about once weekly. In the later attacks, the patient's facial muscles would twitch, and he would turn his head to one side or the other. In some attacks, he bruised or burned himself. Within a year before he was referred to us he had begun to be rebellious, surly, and ill-behaved, although highly intelligent.

Pneumoencephalograms had been performed, with negative results. Several electroencephalograms had been made, and all showed generalized, paroxysmal, nonspecific dysrhythmia, with occasional invasion of wave and spike complexes. Results of other examinations had been noncontributory. The patient had received the following medicaments daily at various times from eight different physicians, without relief: diphenylhydantoin 0.4 gm., phenobarbital 0.3 gm., Mesantoin 0.6 gm., mephobarbital 0.3 gm., and glutamic acid 20 gm.; in addition, regulation of the acid-base balance had been tried. Our clinical examination, including roentgenograms of the skull and electroencephalograms contributed no new information. Because most of the steps of the standard treatment method had already been carried out and because the patient had come a long distance for treatment, a period of intensive treatment was decided on.

While under the constant watch of special nurses, beginning July 30, 1949, the patient was given 0.9 gm. of diphenylhydantoin and 15 gm. of glutamic acid daily, with enough phenobarbital (up to 0.2 gm. every 2 hours) to keep him drowsy. Inhalations of a carbon dioxide-oxygen mixture were given every hour. In addition, 300,000 units of procaine penicillin was given intramuscularly twice daily. A ketogenic diet was ordered, but by Aug. 3 the patient was too drowsy to eat or drink and had to receive fluids intravenously. He had to be catheterized, and, finally, tidal drainage of the bladder was instituted. On Aug. 6, diphenylhydantoin and phenobarbital administration was stopped, but the patient did not awaken until Aug. 11.

This period was utilized for rapid determination of optimum medication, a procedure that was at that time in process of development. A comparison of records made it clear that of the three drugs tested, trimethadione in a dose of 2 gm. had the greatest effect on the slow waves, but diphenylhydantoin in a dose of 1 gm. and Mesantoin in a dose of 1 gm. also produced substantial improvement. Phenobarbital produced minimal improvement and phenacemide none.

On awaking from this period of narcosis, the patient rapidly regained normal vigor and alertness. On discharge, diphenylhydantoin 0.5 gm. and trimethadione 0.3 gm. daily was prescribed. From that time, the patient has had no seizures of any kind or periodic dullness. His irritability rapidly disappeared. He was somewhat sensitive to bright lights, and this symptom was overcome by reduction in the dose of trimethadione. The patient has recently married and is attending college.

Case 3.—A 35-year-old man was first referred to one of us (T. J. P.) by Dr. Wilder Penfield in 1944. Convulsive seizures had developed in this man at the age of 7 years, but with phenobarbital medication he had had a remission at the age of 13, which lasted 4 years. Seizures then recurred, with a prodrome of generalized weakness and nausea as well as hesitation in speech and, occasionally, diarrhea. They occurred at irregular intervals, on an average of four per year. During some seizures, the patient sustained bruises and cuts about the head. He had been given phenobarbital and diphenylhydantoin.

General physical and neurological examinations revealed nothing of apparent significance. Electroencephalograms taken at the Montreal Neurological Institute showed "bisynchronous wave and spike disorder of moderate severity." This examination has since been repeated at intervals, and the results have been uniformly the same. Results of other routine laboratory studies have been noncontributory.

The patient's dose of diphenylhydantoin was systematically increased to the tolerance level (0.4 gm. daily), and regular exercise was prescribed. He improved greatly, and, except for occasional lapses in medication during intercurrent illness, was seizure-free for five years. During this period, he got married, obtained a driver's license, and worked steadily as a broker. In 1947, he began to have auras of seizures, and Mesantoin, 0.1 gm. daily, was added to his drug regimen. Further increases in medication resulted in ataxia. During 1948 and 1949, the patient had four seizures and finally lost his job. In May, 1949, his wife filed suit for divorce, and he went into a severe depression and had to be institutionalized. He came to Los Angeles in July, 1949, for a reconsideration of treatment, but the seizures continued even when he was taking subtoxic doses of his medicine. Finally, the intensive treatment was suggested to him and was begun Aug. 19, 1949.

While under the constant supervision of special nurses, the patient was given 0.9 gm. of diphenylhydantoin and 15 gm. of glutamic acid daily and enough phenobarbital, up to 0.2 gm. every two hours, to keep him drowsy. He was given inhalations of a carbon dioxide-oxygen mixture for five minutes every hour. A ketogenic diet was prescribed, but by Aug. 22 he was to sleepy to eat or drink. As he did not void spontaneously he had to be catheterized, and finally tidal drainage was instituted. Dihydrostreptomycin, 0.3 gm., and penicillin, 50,000 units, were given every three hours. Intravenous injections of 5% glucose solution were given to prevent dehydration.

On Aug. 24, the administration of phenobarbital was discontinued, and the period of recovery was used for a modified rapid determination of optimum medication as used at that time. This showed clearly that trimethadione had the greatest normalizing effect on the patient's dysrhythmia with phenobarbital next best and Mesantoin third. Diphenylhydantoin and phenacemide showed little effect on the record. Therefore 0.8 gm. of Mesantoin and 0.3 gm. of trimethadione daily was prescribed. Up to the following February, the patient had five seizures, at longer and longer intervals, but has had none since then. Meanwhile, he has completed the necessary work and received the degree of master of arts. On his own initiative, he gradually reduced and finally omitted all of his medication up to February, 1953, when he began taking the drugs again. It seems to us unlikely that this striking improvement can be ascribed to emotional causes, since his life is still filled with disappointments and frustrations.

Case 4.—An incapacitated business man, 48 years old, was first seen as a private patient July 11, 1950. He had been generally well and had worked hard until 1940, when he began to have seizures, with sudden loss of consciousness, falling, twitching of the extremities, and sometimes foaming at the mouth. They lasted as long as four minutes and occurred at irregular intervals; he never had less than 4 and had as many as 17 a year. Most attacks were preceded by an aura of a sensation of flushing of the face, which often occurred also without definite attacks, sometimes as often as 23 times a day. Within a year of the onset of his symptoms, the patient was seen at a well-known clinic in another city, where a ventriculogram was made and a left-sided exploratory craniotomy was performed. After the craniotomy, he had frequent paresthesias of the right upper extremity, despite the use of various drugs, including phenobarbital, diphenylhydantoin, and Mesantoin. He dates his complete incapacity from that time. He took 0.4 gm. of phenobarbital daily, and this was later changed to 0.4 gm. of diphenylhydantoin.

For financial reasons, he requested transfer to the outpatient clinic of the Cedars of Lebanon Hospital. There a lumbar puncture was performed, with results within normal limits. An electroencephalogram was made and showed a pronounced dysrhythmia, with a slow wave focus over the left hemisphere. The dose of diphenylhydantoin was gradually increased to the tolerance level, 0.5 gm. daily, and this was supplemented by 0.1 gm. of phenobarbital. This controlled the patient's grand mal seizures, but the frequent focal sensory seizures (up to 10 daily) prevented his working. In the hope of bringing about an economic rehabilitation, a rapid determination of optimum medication was advised. This was begun on Oct. 30, 1950. Phenobarbital was found to have the greatest beneficial effect on the electroencephalogram, but Mesantoin, glutamic acid, and paramethadione produced slight improvement.

Since the patient had already had a long clinical trial with phenobarbital and Mesantoin, the next logical step seemed to be to subject him to a period of narcosis treatment. He was hospitalized for this purpose on Nov. 6. Constant special nursing was provided. He was given 0.3 gm. of phenobarbital orally every two hours until asleep, 1.5 gm. of diphenylhydantoin every eight hours, 10 gm. of glutamic acid every eight hours while able to swallow, inhalations of 10% carbon dioxide, 300,000 units of penicillin daily, and fluids intravenously as needed. He was deeply asleep within two days but could still be persuaded to swallow the diphenylhydantoin capsules. After this, no food was given by mouth. On Nov. 11, while he was still asleep, his temperature arose to 104 F. It was found that his urine was infected. A tidal drainage apparatus was installed, and use of all sedatives was discontinued. The temperature was normal within three days, and the patient gradually recovered consciousness. He was discharged from the hospital Dec. 4, and Mesantoin 0.6 gm., glutamic acid 15 gm., and paramethadione 1.8 gm. daily was prescribed.

The patient has been followed in the clinic. In May, 1951, he had one grand mal attack, and he complained of slight discomfort in the old craniotomy scar. That was his last major attack; on July 1, 1952, he reported that he had had no attacks of any kind for 13 months and was working regularly as a bookkeeper.

A synopsis of the entire series of patients treated by the intensive method is given in the table. It will be seen that seizures are controlled in 66% of patients with difficult, recalcitrant seizures, and in only about 15% can the treatment be considered to have failed. The results compare favorably with those from surgical treatment (see the table).

AVOIDANCE OF COMPLICATIONS IN INTENSIVE TREATMENT

While the cardinal points in intensive treatment were utilized from the first case, experience has caused us to modify the details. It was clear at once that patients receiving the treatment should have a nurse in constant attendance, and this is still required. A suction apparatus should be available. The only serious complication of the treatment was pneumonitis, which was seen in three of the early patients. In all of these, a ketogenic diet and glutamic acid was being given by nasal tube. We then learned to allow ketosis due to starvation to develop and to administer fluids intravenously. In future cases, we plan to give glutamic acid intravenously also. As a further precaution against pneumonitis, we give 300,000 units of procaine penicillin intramuscularly daily. We still feel safer in having a skilled anesthetist available on call, in case intratracheal insufflation or aspiration is required.

As time went on, we learned to induce sleep with massive doses of diphenylhydantoin, usually 4 gm. for an adult. If this does not produce a comfortable relaxation, we give paraldehyde [24] orally or rectally or phenobarbital intramuscularly as a supplement. If the patient is in such deep coma that he cannot swallow, subsequent doses of diphenylhydantoin (usually 1.5 to 2 gm. daily during the period of narcosis) are given in suppositories.

Inhalations of 10% carbon dioxide in 90% oxygen are given by mask for 10 minutes every hour. Perhaps this dose should be increased, at least in some cases. We have tried administration of a lower concentration continuously in a tent, but the gas escapes too rapidly. At present, we are experimenting with continuous administration of low concentrations by means of a special mask. Patients are allowed to void spontaneously. Occasionally, catheterization or tidal drainage is necessary. Defecation is managed with enemas.

As a rule, four days has been taken empirically as a satisfactory duration of deep sleep. When the treatment has been interrupted earlier, the results have seemed less good; when the sleep has continued longer, the risk of complications (pneumonitis and excessive loss of weight) has seemed greater. Usually, all medication is then stopped, and sometimes amphetamine is given to shorten the period of awakening, which is often a difficult one, since the patient may be delirious. If necessary, paraldehyde is given to control excitement. As the patient approaches a normal state, his preoperative medication is begun again and continued indefinitely.

COMMENT

Even in the most successful cases, favorable results may not be seen immediately. Sometimes there is an actual exacerbation of preexisting behavior disorders, which lasted in one case as long as six weeks. Sometimes, also, the patient will have an isolated seizure within three months after the intensive treatment, then will have no more. The results in such cases are considered to be successful.

A long period of freedom from attacks was followed by relapse in three cases. One was that in the patient described in case 1, the first in the series. Since having a second course of treatment, the patient has been seizure-free and working for four years. In another case, a repetition of the treatment moderated but did not control the seizures. In the third, the attacks have remained under control for over a year. Relapse occurred in a fourth patient, who was placed in an institution, where her maintenance medication was discontinued.

There was clear evidence of a gross lesion of the brain in seven patients. In three, craniotomies had been carried out. In others, "spikes" were demonstrated in the temporal region in an electroencephalogram taken during sleep. Such patients may be considered candidates for temporal lobectomy. It has, however, been our feeling that it is more conservative to administer the intensive treatment first. If this is unsuccessful in patients in whom surgical procedures seem indicated, we hope to carry them out. There has seemed to be little difference in results obtained between the cases in which the epilepsy was presumably symptomatic and those in which it was cryptogenic. The worst results were obtained in seven patients who had severe deterioration. Among these cases two complete failures occurred, but there were also three cases in which gratifying successes were obtained.

While no patients in this series have died, there certainly is some potential risk in the treatment. Prolonged narcosis for other purposes has resulted in an appreciable mortality, which might be decreased by the precautions now available (avoidance of gavage, use of suction and carbon dioxide inhalations, and administration of antibiotics). This is necessarily an expensive treatment. A two week stay in the hospital, with continuous special nursing, should be provided for, and this period occasionally is exceeded. The expense might be greatly diminished if the treatment were given in special institutions or sanatoriums rather than in general hospitals and if one or two nurses could take care of a group of patients undergoing treatment simultaneously. Despite these disadvantages, most patients whose seizures are uncontrolled accept the treatment gladly.

SUMMARY

An outline of rules for the conduct of the standard ambulatory treatment of epilepsy, as employed by the authors, is given. In cases in which circumstances have permitted these rules to be followed strictly to their conclusion, as high as 56% of patients have been maintained seizure-free for significant periods. Even among patients in whom the treatment has been only partially carried out but has been continued for more than a year, 68% are free of major seizures and are also able to work or go to school.

In the 25 patients unrelieved by the complete standard treatment as outlined, a new form of intensive, or narcosis, treatment has been administered. This consists of the administration of massive doses (up to 4 gm. daily) of diphenylhydantoin, sometimes combined with paraldehyde or another soporific. Ketosis from starvation is allowed to develop, and the patient is given inhalations of a carbon dioxide-oxygen mixture every hour. Other details of treatment and precautions necessary are described. The period of sleep usually lasts four days and the entire treatment about two weeks. Following such treatment, 64% of patients previously unrelieved by the standard treatment have been maintained seizure-free. In the entire series of 75 patients, attacks were finally controlled in 58 (77%).

Education for Professional Services.—Since Plato first wrote of the necessity for educating men to wisdom, scholars and thinkers throughout the Western world have repeated his message again and again. . . . But today our educational system is fragmented, stressing occupational values, and in danger of letting our civilization follow the path, like Rome and Athens, to decay and destruction. . . . The modern barbarians do not destroy science and technology, they do not wipe out the machine values but instead convert them into terrible forces of evil and death so that those who would resist their mad rush must out-do them in ruthlessness. What they do destroy with devastating thoroughness is the liberal culture of the people. They destroy their roots into the past, their libraries, their free press, their religion, their belief in the essential dignity of man. In short—destroy the education which makes men free. . . . It seems self evident that one of the elementary functions of primary and secondary education is to inculcate the desire to read and to develop at least the rudiments of taste for the literature of our own tongue. That we fail to accomplish this in any large measure is, I believe, the conviction of most men who teach in college and university and are thus in a position to evaluate the accomplishment of the schools. . . . The bald fact is that we, as a people, no longer hold liberal education in high regard; we do not think very well of the education which nourishes man's spirit. Instead, accepting the pragmatic utilitarianism of our day, we have filled the student's time with whatever seemed to him and to his parents to be most immediately profitable; the vocationalized, the specialized, the elective and the electric, with the transient fads and interests of the day. We have established no standards, acknowledged no immutable values and adhered to no common faith. With amazing arrogance we have turned our backs on the past, thus ignoring Santayana's wise observation that "Those who cannot remember the past are condemned to repeat it." With sublime faith in the belief that in this new age of science and enlightenment man's salvation would be achieved with slide rule and analytic balance, we have piled specialization upon specialization with the inevitable result—fragmentation of education.—S. Dorst, M.D., Education for Professional Services, *The Pharos of Alpha Omega Alpha Honor Medical Society*, May, 1953.

ANESTHESIOLOGIST'S RESPONSIBILITY TO THE PATIENT

CHAIRMAN'S ADDRESS

R. J. Whitacre, M.D., Cleveland

Anesthesiology is on the threshold of its greatest contributions to the safety and mental well-being of the patient. In the past, the initial responsibility of the anesthesiologist was to make the patient comfortable and to provide adequate muscular relaxation and reflex depression during surgery. These two objectives are being accomplished in the vast majority of operations; however, the obligations of the anesthesiologist are now distributed over a wider area. Greater attention must be given to the broader, and perhaps more important, aspects of patient care. Successful surgery defeats its own end if the anesthesia service is deficient. I am confident that in the future greater emphasis will be placed on safety to the patient and that more attention will be devoted to the understanding of the patient's problems. My discussion will be limited to these two points. Measures to decrease the danger of surgery and to increase the satisfaction of the patient are of fundamental importance to his welfare and are essential to the development and progress of anesthesiology.

INFORMATION REQUIRED

During the past 20 years, anesthesiology has progressed through several interesting phases. Opinions have differed widely regarding the importance of anesthesiology and the pattern that should be followed in its application. As in most phases of medical care, time and experience will eventually dictate the proper solution to our problems. The history of medicine has repeatedly shown that if it is possible to devote more attention to the factors of fundamental importance, we will more readily obtain our objective, better care of the patient.

The safety of anesthesia administration requires a particular and intimate consideration, because many of the inherent dangers are not adequately understood. Regrettably, we are handicapped by a deficiency of factual information about complications and deaths that occur during and after anesthesia. While many exhaustive surveys and analytical reports are published annually on a great variety of medical subjects, there is an unfortunate lack of comparable material on the hazards related to anesthesia. Perhaps because the personal experience of each surgeon or anesthesiologist is necessarily limited, the importance of anesthesia as a cause of morbidity and mortality is often underestimated.

During the past decade, several factors have forced us to revise our opinion of the importance of the dangers associated with anesthesia. One factor is the great increase in the number of elective operations on good risk patients. A fatality in this group naturally causes greater public and professional concern. There also has been a definite increase in the number of complex and technically difficult surgical procedures of longer duration. The successful outcome of these operations is more than ever dependent on the quality of the anesthesia administration. The third change is that larger numbers of poor risk patients benefit from the advances in surgical practice. Many of these patients would have been considered inoperable a few years ago. The need of precautionary measures and more painstaking anesthesia care for such patients is obvious. Many of these developments have occurred so swiftly that we have failed to appreciate the necessity for careful evaluation of the effects of anesthesia. A thorough understanding and analysis of these problems are vital if we are to avoid a false sense of security regarding the risk accompanying anesthesia.

The advice of every anesthesiologist is sought at one time or another regarding problems in his field. As consultants, we sometimes mislead those who seek our advice by stating or implying that the use of certain drugs or techniques will eliminate the danger of anesthesia. The impression is often gained that we, the consultants, do not encounter difficulties. The fact is, a discussion within any group of anesthesiologists with substantial clinical experience soon discloses that few anesthesia complications ever find their way into the literature.

Another indication of the reluctance of anesthesiologists and surgeons to present the problems encountered in the operating room has been the difficulty experienced by those who have endeavored to establish anesthesia study commissions. Many years ago, we were impressed with the potential value of the Anesthesia Study Commission established in Philadelphia under the direction of Dr. Henry Ruth. About 14 years ago, when we began an effort to study anesthesia problems systematically on a regional level, the prevailing attitude varied from indifference to active opposition.

The cooperation of clinicians has vastly increased in recent years. More factual information is necessary, however, before we can evaluate the real importance of anesthesia with a reasonable degree of accuracy. The nature of most anesthesia complications is such that great care must be exercised to avoid apprehension or loss of public confidence. Because it is our duty to provide the greatest degree of safety for every patient who enters the operating room, no one should deceive himself about the actual dangers associated with anesthesia.

MORE ANESTHESIOLOGISTS NEEDED

Fortunately, great progress has been made toward realization of the anesthesiologist's foremost ambition, making anesthesia safe. This progress has included the development of new drugs, new techniques, and better understanding of the basic sciences as they relate to anesthesiology. But a factor of equal importance is the

---

Read before the Section on Anesthesiology at the 102nd Annual Session of the American Medical Association, New York, June 3, 1953.

application of all available knowledge to each patient. This can be accomplished only by a larger number of qualified anesthesiologists. This need is emphasized further by the increased number of operating room problems that cannot be managed effectively unless the anesthesiologist has one or more associates to assist him.

Another sphere with which we are concerned is the obligation inherent in the patient-physician relationship. This includes sympathetic understanding of the patient as well as professional evaluation of his condition and his requirements in relation to adequate preparation for impending surgery. From the patient's point of view, the anesthesiologist's preoperative visits provide the personal consideration that results in greater confidence, understanding, and freedom from fear. While it may not be generally conceded that the patient requires an explanation of the type of anesthesia to be administered, there can be no doubt that a candid response by the physician to intelligent questions will prove beneficial. If the patient is apprehensive about a certain anesthetic, this should be taken into consideration and the prejudice respected if possible. An anxious and unrelaxed state induced by uncertainty is harmful and disturbing. The patient should be enlightened regarding the procedure ahead and the reasons for certain restrictions.

There are many instances in which timely preoperative attention has meant the difference between life and death. Greater safety in the operating room will not be achieved until the anesthesiologist can discharge his obligation toward each patient and his problems. Postoperative visits result in better supervision of the physical needs of the patient. In addition, they foster good will. Preoperative and postoperative visits are a phase of anesthesia service that is of great importance, but its benefits will not be realized by all patients until there are greater numbers of trained anesthesiologists.

Only by increasing our numbers can the obsolete standards of 15 or 20 years ago be discarded. At that time, the hospital staff that included one anesthesiologist was considered adequately staffed. This was a great step forward; however, under that system personalized service was impossible. Today there is no valid reason for every person entering the operating room not receiving expert attention. This responsibility to the patient can only be fulfilled if we attract enough physicians and train them to be competent anesthesiologists.

The number of resident training programs was limited in the past. This made it difficult to provide anesthesia instruction to a sufficient number of physicians. This defect has now been remedied, and, at the present time, there is no shortage of educational facilities. The problem now is to find ways and means of interesting a greater number of physicians in the practice of anesthesiology. I do not mean to infer that there is a decreased interest in anesthesiology. The situation is one in which the demand for qualified anesthesiologists is growing so rapidly that we are unable to keep pace with it.

Perhaps we should consider the successful manner in which so many well-trained surgeons were produced. This was accomplished by making surgery attractive to the young physician. Since this field offered ample professional recognition and incentive, adequate numbers of competent surgeons are now available in virtually every community in the country. If we are to meet our responsibility to the patient by providing a degree of anesthesia service comparable to the progress made in surgery, the obvious approach is to make sure the incentives and opportunities provided by our specialty attract an ever-increasing number of physicians. Any attempt to induce greater numbers of capable men to study anesthesiology is doomed to failure unless it places proper emphasis on professional prestige and community esteem. We know there is sufficient stimulus from a scientific point of view. There are probably those who would maintain that this is the only inducement needed to attract men of high caliber. I do not believe that this premise will effect a satisfactory solution. Recognition and opportunities are powerful incentives to provide outstanding service. When the practical benefits of the study of anesthesiology are more apparent and less controversial, the problem of procuring the right type of applicant will be resolved.

Lay and medical people alike have questioned the relationship between the program of attracting young men and better care of the patient. The critics of the broad policies outlined here have, however, suggested no constructive plan to fill the need for an adequate number of anesthesiologists. The solution demands the thoughtful and cooperative interest of everyone concerned because it has the fundamental purpose of improving the welfare of the patient. The soluton to our problem, in brief, calls for the elementary application of basic American principles of recognition for merit, consistent with the policies that have made American medicine so successful. All the suggestions proposed to solve the problems by other means have proved ineffectual in meeting the long-range needs.

To appreciate the significance and character of the changes brought about in the status of anesthesiology, it is necessary to gain a perspective of its development, particularly as it relates to care of the patient. The quality of the service rendered by the anesthesiologist to each patient is the factor that will determine the future progress of the specialty. The time is definitely past when temporary expediencies provide a satisfactory answer for poor or even mediocre anesthesia service.

CONCLUSION

In meeting the anesthesiologist's responsibility to the patient, three factors should be considered: 1. Expert anesthesia service should be available to every patient in every hospital, and providing this care is our primary responsibility. 2. The results of research and clinical investigation can be applied with full benefit to each patient only if a great many more physicians are attracted to anesthesiology. 3. Maintaining and building a better physician-patient relationship during the orderly growth of anesthesiology is the most effective way to improve the quality of anesthesia service.

CARDIAC RESUSCITATION

Sanford E. Leeds, M.D., San Francisco

The subject of cardiac resuscitation is of great importance because delay of only a few minutes in beginning treatment may make the difference between a dead or disabled patient and a living and well one. It is important to have a predetermined plan of action and to have equipment available in order to avoid delay. Cardiac arrest or ventricular fibrillation may occur during any surgical procedure, even in a tonsillectomy with the patient under local anesthesia. It can occur during bronchoscopy or esophagoscopy; hence, anyone who performs major or minor surgery or anesthesia must be familiar with the technique of cardiac resuscitation. The cardiologist or internist who performs catheterization of the heart not only should be aware of the possibility that cardiac arrest or ventricular fibrillation may develop during the procedure but also must be prepared to treat it, since there is usually no time to call someone else to resuscitate the patient. As yet, I am not aware of any case that has developed on a hospital ward in which the patient has been successfully resuscitated.[1] This indicates the need for preparation to handle this emergency when it occurs outside of the operating room by keeping available a resuscitation kit. The kit should contain a scalpel and other instruments, some drugs with syringes and needles, a means of providing oxygen under pressure for artificial respiration, and a defibrillator. Such mobile equipment is already available in some hospitals.

There appears to be an increase in the number of patients who require resuscitation. This increase may be due to the large number of patients undergoing anesthesia, catheterization of the heart, and thoracic and, particularly, cardiac surgery. Since an effective treatment is now available, surgeons, anesthetists, members of the house staff, and others are more alert to the development of this complication and the need for treatment without delay; hence, more cases are being reported and quoted than formerly. Although "anesthetic deaths" were recognized shortly after the introduction of anesthesia 100 years ago, it is only recently that the causes of cardiac arrest and ventricular fibrillation have become better understood and a satisfactory treatment evolved. In fact, it was only five years ago that the first patient with ventricular fibrillation proved by electrocardiography was resuscitated.[2] It is now appreciated that the major causes of cardiac asystole or ventricular fibrillation are anoxia of the myocardium and reflex mechanisms [3] initiated through vagus stimulation. The best preventive is the provision of a constant stream of highly oxygenated blood through the coronary arteries. Anything that interferes with the airway or depresses respiration, such as overdosage or excessive use of multiple anesthetic agents, may bring on asystole and should be avoided.

Although the treatment of cardiac arrest and ventricular fibrillation is well established, there is much to be learned about the cause and prevention of this catastrophe. More knowledge is needed of the physiology of the myocardium, particularly with reference to the use of drugs, the magnitude and duration of the optimum electric shock needed to provide the proper "effective" current, and the factors that increase or diminish irritability of the myocardium. Because of the fortunately small number of arrests that occur (estimated at 1 in 3,000 operations [4]), it is difficult to acquire statistics regarding the effectiveness of different drugs, electrodes, or shocks under various conditions. It is, therefore, important to record carefully all observations made of clinical cases and publish them, as many hospitals are now doing. There is much information available from animal experiments in this field, and more is being accumulated, but there are certainly species differences in behavior that must be taken into account when knowledge derived from the laboratory is applied to human subjects.

Some of the facts to be acquired concern the electrical characteristics of the heart. The resistance of the dog's heart, for example, was only recently accurately measured by means of oscillographic equipment.[5] That of the living human heart has not to my knowledge been measured. Although the electric shocks and drugs that are in use are effective in most instances, it must be remembered that they have largely been determined empirically and that there is still much to be learned about cardiac resuscitation.

TECHNIQUE OF CARDIAC RESUSCITATION

When cardiac asystole develops during the induction of anesthesia or during an operation, it is usually the anesthetist who first becomes aware of the absence of the pulse and blood pressure. The surgeon can verify this quickly by noting whether there are pulsations in an artery in or near the operative field. If the heart is in the field, the surgeon may be the first to observe that it has stopped, and he may notify the anesthetist. When cardiac arrest occurs, the vital functions of circulation and respiration must be maintained artificially until the heart can resume its normal function if the patient is to survive with an intact cerebrum.

The anesthetist starts artificial respiration through a mask or endotracheal tube (preferably the latter) and supplies 100% oxygen with positive pressure. Should cardiac arrest develop on the ward or in some location away from the operating room, mouth-to-mouth forced respirations may be carried on until an anesthesia machine or other respirator can be brought to the scene.

The anesthetist or some other person designated to perform the task keeps track of the time and notes the time at which procedures are started or drugs administered.

The surgeon may take a few seconds to prick the heart with a needle mounted on an empty syringe in order to see if it will resume a normal rhythm. Pricking the heart with a needle is indicated if asystole is present but is of no use if there is ventricular fibrillation. Since fibrillation is present in only a small percentage of cases (estimated at 10%), the maneuver is permissible but only if not more than 10 or 15 seconds are required.

After confirming the absence of arterial pulsations, the surgeon exposes the chest and makes an incision in the fourth or fifth left intercostal space reaching from the left border of the sternum to the axilla (fig. 1*A*). There is no bleeding, and the incision is quickly carried through the pleura; care should be taken to avoid injury to the left lung. The surgeon inserts his hand into the chest and starts massage. The heart is firmly squeezed in order to express as much blood as possible by each contraction of the hand. The rate of contraction should be as rapid as possible, but each contraction should be completely effective.[1] In cases in which the heart is small, as that of an infant, the rate can be maintained easily at 80 to 100 per minute, while, if the heart is larger, the rate will probably be slower. Occasionally it may be necessary to compress the heart with two hands. Effective massage is tiring and the surgeon should be relieved by an assistant so that efficiency is maintained. Proficiency in massage may be acquired by practice on experimental animals. It is easier to insert the hand into the chest if an assistant holds the fourth and fifth ribs apart until a self-retaining rib spreader can be inserted (fig. 1*B*). Additional exposure is gained if the adjacent costal cartilages are divided. If cardiac massage is not effective with the pericardium intact, the pericardium should be opened so that the surgeon may better grasp the ventricles with his hand. Should bleeding from the chest wall occur during massage of the heart, the assistant may clamp and tie the vessels. The skin may be painted with an antiseptic solution, and sterile towels may be applied after massage is initiated.

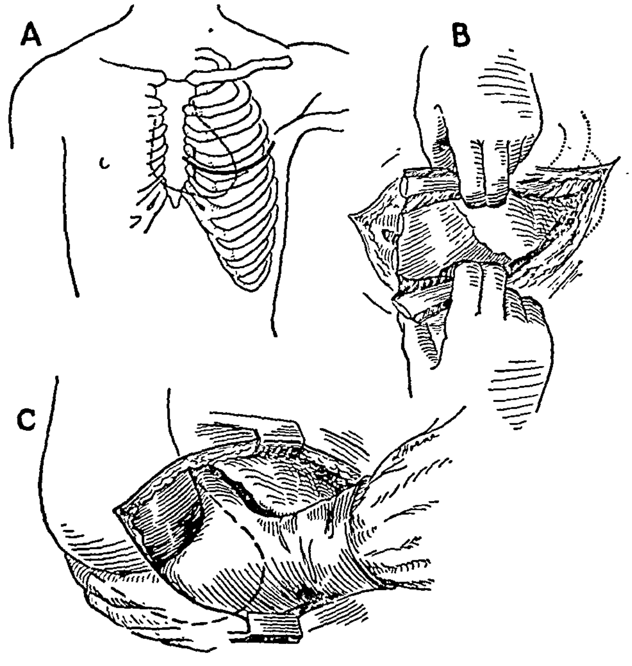

Fig. 1.—*A*, incision in fourth or fifth left intercostal space extends from the sternum to the axilla. *B*, assistant holds the ribs apart until a rib retractor is available. One or two adjacent rib cartilages may be divided to improve the exposure. *C*, surgeon grasps the heart and compresses it rhythmically 80 to 100 times per minute.

The need for haste is plain. The anesthetist or surgeon may not discover the absence of arterial pulsations for a minute or more. It has been determined experimentally[6] that the central nervous system is damaged after four to six minutes of anoxemia. A rule of thumb is that the circulation and respiration must be started artificially before two or three minutes have elapsed if the patient is to survive without damage to the brain.

Once respiration and circulation are maintained artificially, the patient's condition improves, the pulse and blood pressure are obtainable, and there is no longer need for haste. A case was reported by Beck[2] in which massage was carried on for an hour before the heart resumed its normal function; no permanent injury to the heart occurred. One may look for ventricular fibrillation at this time. The worm-like contractions of the myocardium may be seen through the thin pericardium, or, if there is any doubt, the pericardium may be opened.

While respirations and cardiac massage are being maintained, fluids, such as a solution of 5% dextrose in distilled water or blood, should be administered intravenously. These fluids will increase the return of venous blood to the heart and support the circulation.

The next problem confronting the resuscitation team is that of returning the heart to a normal rhythm. When the heart is in asystole, it may stay in that condition for a variable length of time. According to present knowledge, it will either return to normal rhythm or change to ventricular fibrillation. If the heart returns to a normal rhythm that is weak with poor contractions, epinephrine should be given in amounts of 0.5 to 1 cc. of a solution made by mixing 1 cc. of a 1:1000 solution with 4 cc. of isotonic sodium chloride solution. This preparation should be injected into the auricle, and injection may be repeated every three minutes. If the heart remains in asystole for 5 or 10 minutes and appears to be losing its tone, epinephrine or calcium chloride may be administered very cautiously in small dosage, since ventricular fibrillation may develop if the irritability of the myocardium is increased. Procaine hydrochloride and procaine amide (Pronestyl) hydrochloride are contraindicated in asystole because they may further depress a myocardium that is not contracting. In adults, atropine should be administered intravenously in amounts of 0.01 grain (0.6 mg.), especially in cases in which the vagovagal reflex appears to be responsible for the arrest.

Mention should be made of the drugs that are useless or contraindicated in cardiac resuscitation. Analeptic and sympathomimetic drugs, such as caffeine, nikethamide (Coramine), pentylenetetrazol (Metrazole), strychnine, ephedrine, amphetamine (Benzedrine), phenylephrine (Neo-Synephrine) hydrochloride, and *p*-(2-aminopropyl) phenol (Paredrine), should not be

---

6. Weinberger, L. M.; Gibbon, M. H., and Gibbon, J. H., Jr.: Temporary Arrest of the Circulation to the Central Nervous System: I. Physiologic Effects, Arch. Neurol. & Psychiat. 43:615 (April) 1940.

used. Drugs that stimulate the central nervous system increase the oxygen demand; in cases in which there is anoxia, the danger of damage is aggravated. Medicaments such as digitalis and strophanthin act on the auriculoventricular conduction system to increase the refractory period and to slow the rate of conduction; they should also be avoided.

Should ventricular fibrillation develop, single or serial shocks may be applied with the defibrillator prior to the administration of procaine. Should the shocks fail to produce a normal rhythm, procaine or procaine amide hydrochloride should be given to aid in defibrillation. Procaine hydrochloride is administered, 10 cc. of a 1% solution, into the auricle; 200 mg. of procaine amide hydrochloride should be administered either intravenously or directly into the auricle. Ventricular fibrillation may revert to a normal rhythm with massage alone[7] in human patients. It is doubtful whether this reversion occurs in dogs in which fibrillation has been produced by a weak electric shock. After the administration of procaine or procaine amide hydrochloride electric shocks are again administered with the defibrillator. The defibrillator can be constructed to deliver a shock of 110 volts or 130 volts with a timer that allows the administration of voltages of 0.1 second duration. In order to avoid or minimize damage to the myocardium from burns or other effects, a shock of 110 volts for 0.1 second is given first. If single shocks at the lower voltage are not effective, 5 to 10 serial shocks at one second intervals are administered. The higher voltage of 130 is used if a shock of 110 volts is not effective. If poor contact is made while employing very small electrodes, a shock of even 130 volts may be inadequate because of the high resistance present in the circuit. It is evident that the electrodes and their contact are extremely important. If the pericardium is open and electrodes covered with gauze moistened with sodium chloride solution are pressed firmly against the heart, the shocks are more likely to be effective, since an adequate current will pass through the heart.

Drugs That Are Useful in Cardiac Resuscitation

Drug	Dosage	Indications	Contraindications	Remarks
Epinephrine	0.5 to 2 cc. 1:5,000 solution in auricle	Regular rhythm; weak contractions; cautiously in asystole	Ventricular fibrillation present	Stimulates heart by direct effect on myocardium and conduction system; increases myocardial irritability
Calcium chloride..............	2 to 4 cc. 10% solution in left ventricle	Regular rhythm; weak contractions; cautiously in asystole	Ventricular fibrillation present	Will sometimes revive heart that does not respond to epinephrine *
Procaine hydrochloride.......	10 cc. 1% solution in auricle or 50 to 100 cc. 1% solution intravenously	Ventricular fibrillation that fails to respond to shocks	Asystole present and myocardium flabby	Diminishes irritability of myocardium and conduction system
Procaine amide hydrochloride (Pronestyl)	100 to 200 mg. in auricle or intravenously	Ventricular fibrillation that fails to respond to shocks	Asystole present and myocardium flabby	Diminishes irritability of myocardium and conduction system
Atropine and scopolamine....	.0065 gm. or 0.01 grain intravenously	Cardiac arrest due to vagovagal reflex	Tachycardia present	Block vagal effects on sinoauricular pacemaker
Quinidine	0.2 gm. 4 or 5 times daily, orally	Presence of cardiac arrhythmia preoperatively	Intravenous or intracardiac use	Decreases myocardial excitability and slows conduction of impulses
Barium chloride...............	1 to 2 cc. 0.5% solution	Regular rhythm; weak contractions; cautiously in asystole	Ventricular fibrillation present	Used less frequently than calcium chloride
Potassium chloride...........	0.5 to 5% solution	Ventricular fibrillation; to produce cardiac inhibition	Asystole present or regular contractions weak	Not recommended; electrical defibrillation is probably more efficient and less dangerous

* Kay, J. H., and Blalock, A.: The Use of Calcium Chloride in the Treatment of Cardiac Arrest in Patients, Surg., Gynec. & Obst. 93: 97, 1951.

It has been shown[8] that weak currents below 55 volts and 1 ampere administered to the heart of a normal dog will result in ventricular fibrillation. An effective and safe defibrillating current must be above 55 volts, preferably nearer 110 volts and 2 amperes, if the drop in voltage and amperage across the electrodes caused by the resistance of the tissues or by contacts is not to act as a fibrillating current. For these reasons, voltages below 70 or 80 are extremely dangerous and should not be delivered by any defibrillator intended for use in hospitals. If a timer is incorporated in the defibrillator so that currents lasting 0.1 or 0.5 second are used (preferably the former), no burn will occur even in an infant's heart.

The defibrillating current is effective because it produces cardiac arrest that may be followed by a normal rhythm. By passing a strong shock through the myocardium, all the wayward contractions of the myocardium are stopped, and, once a regular rhythm is resumed, the contractions may be improved, if weak, by the administration of epinephrine. After the heart has resumed a normal rhythm, the chest is closed with absorbable surgical sutures. An underwater seal drain may be used. Oxygen is administered as needed and antibiotics are employed for several days.

THE DEFIBRILLATOR

In order to construct an effective defibrillator, certain basic facts must be known regarding the effects of electric shocks on the heart. Much information has been gained from experiments on dogs.[9] As more data are acquired from cardiac resuscitation in human subjects, the technique may require some modification.

[8] Leeds, S. E.; Mackay, E. S., and Mooslin, K. E.: Production of Ventricular Fibrillation and Defibrillation in Dogs by Means of Accurately Measured Shocks Across Exposed Heart, Am. J. Physiol. **165**: 179, 1951.

The range of effective voltages and amperages must be known so that only effective currents are delivered to the myocardium. By "effective current" is meant current that actually traverses the myocardium, not current that is delivered by the defibrillator when the electrodes are in direct contact with each other and meet only minimal resistance. Below about 55 volts and 1 ampere, the shock may produce fibrillation in a heart that is beating normally. Weak currents long enough in duration to span an entire cardiac cycle will usually produce fibrillation in both dogs and humans. In order to produce defibrillation, the current must be higher than 55 volts and 1 ampere (demonstrated in dogs). Very strong currents will defibrillate satisfactorily but may burn or otherwise injure the heart; therefore, a current must be selected that will be high enough to be effective but not so high that it will be injurious. Another factor to be considered is the duration of the shock. Weak shocks, if very short (0.1 second or less), will not always cause fibrillation when applied to a heart with a normal rhythm, because they may occur during the refractory period of the cycle in which the shock is not effective. To produce fibrillation, therefore, weak shocks that last through one or more cardiac cycles (0.5 to 1.0 second) should be used. The reverse is true when the optimum duration of a defibrillating current is selected. If defibrillation is desired, both long and short currents are equally effective, but long currents may damage the heart; hence, the shortest current that is effective should be used. It has been determined experimentally that brief currents lasting from 0.1 to 0.5 second are effective and are less apt to cause burns. Wiggers [10] showed that, if single shocks do not result in defibrillation, serial shocks should be used. Five to 10 serial shocks administered for 0.1 second at one second intervals may be successful at times at which a single shock fails. This has been explained by the fact that isolated islands of fibrillation in the myocardium may persist after a single shock but that, after several shocks, the entire myocardium is arrested.

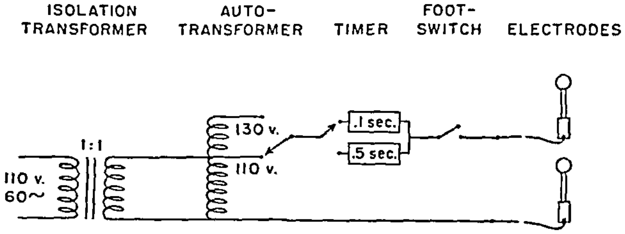

Fig. 2.—Defibrillator including the important component parts.

In a discussion of defibrillation, the final and one of the most important factors to be considered is the electrodes. The electrodes should be as large as can conveniently be placed on the heart so that local heating is minimized and contact resistance is reduced. They should be covered with felt or gauze that may be saturated with sodium chloride solution in order to improve conduction. In order to make the contact as good as possible, the electrodes should be held firmly against the heart on opposite sides of the ventricles. The handles and shafts should be well insulated so that the person holding the electrodes will not receive an accidental shock and so that sparks will not be produced in the operating room. As a further precaution, the back of each electrode should be insulated. In order to avoid shocks to personnel, it is wise for each electrode to be held by a different person each wearing rubber gloves and standing on a dry floor away from the metal operating table. In this way it is almost impossible for them to receive a shock, especially if, in addition, an isolation transformer is used in the circuit of the defibrillator. By using an isolation transformer, a shock could be received only through contact with both electrodes simultaneously during the short period of time that the relay is closed.

The parts of an ideal defibrillator are determined from considerations mentioned earlier in this paper; first, an isolation transformer should be included, since this safety device makes it practically impossible for the person holding an electrode to receive a shock, and, second, the voltages available should be considered. Probably, the minimum voltage should be 110, as use of voltages below this value, even in infants, may result in a fibrillating current if the resistances across the electrodes are too high. The maximum voltage required should be about from 130 to 150 volts. If the defibrillator is built to deliver only one voltage, 130 volts would be the most desirable. With a thorough recognition of the need for large electrodes applied firmly with good contact through saline soaked material, it would appear unnecessary to use voltages higher than 130. If the available electrodes are small, voltages up to 150 might be necessary. If defibrillation does not occur when a shock of 130 volts is administered, it is probably wiser to open the pericardium and to make good contact than to apply extremely high voltages, which in themselves may be harmful to the patient. The limit of 150 volts is arbitrary. Actually the type of study that would determine this figure accurately has not been carried out in human subjects thus far.

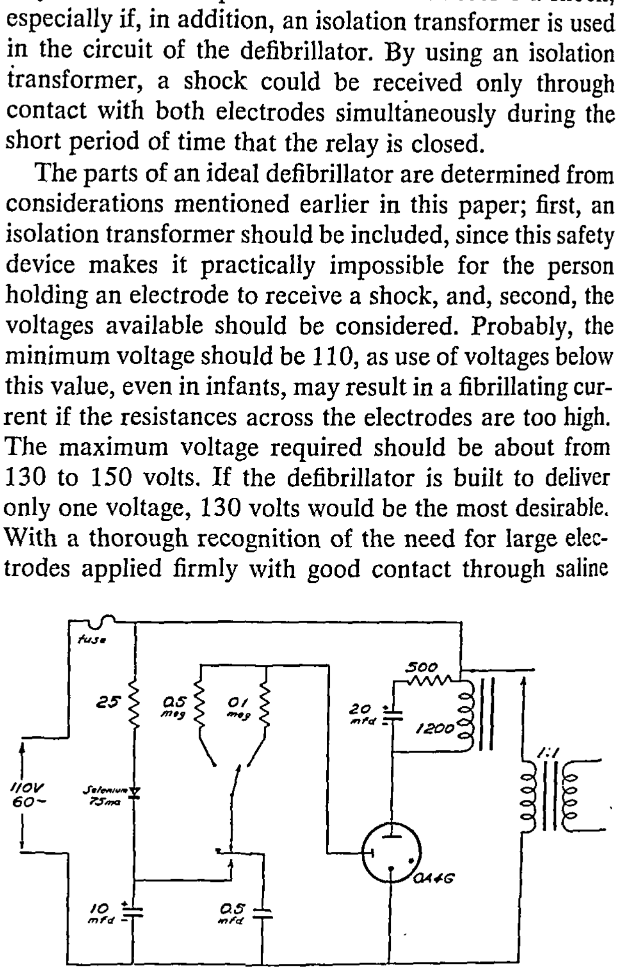

Fig. 3.—Defibrillator circuit devised by Dr. R. S. Mackay. Reproduced from Mackay, R. S.; Moaslin, K. E., and Leeds, S. E.: The Effects of Electric Currents on the Canine Heart with Particular Reference to Ventricular Fibrillation, *Ann. Surg.* **134**: 173 (Aug.) 1951.

---

[9] Mackay, R. S.; Mooslin, K. E., and Leeds, S. E.: The Effects of Electric Currents on the Canine Heart with Particular Reference to Ventricular Fibrillation, Ann. Surg. **134**: 173, 1951. Mooslin, Mackay, and Leeds.[5] Leeds, Mackay, and Mooslin.[8]

[10] Wiggers, C. J.: The Physiologic Basis for Cardiac Resuscitation from Ventricular Fibrillation—Method for Serial Defibrillation, Am. Heart J. **20**: 413, 1940.

As a third part, the ideal defibrillator should include an automatic timer. This is not difficult to construct, and its use is far superior to estimation of the duration of shocks during the sometimes hectic process of cardiac resuscitation. The timer may be set at 0.1 or 0.2 second; longer periods up to 0.5 second are satisfactory but probably not necessary.

Fourth, a foot switch is necessary. The type of switch that discharges the entire shock when the switch is depressed is most satisfactory. As stated above, it is best for the shock to be timed automatically and discharged completely when the switch is stepped on. A spring sets the switch for the next shock as soon as the foot is lifted.

Fifth, the design of the electrodes must be considered. The impression is that any good conductor may be used. Several sizes should be available so that the heart of an infant or of an adult may be accommodated. The smallest should be 5 cm. in diameter and the largest 8 cm. in diameter. The insulation of the handle, shaft, and cord should be adequate to withstand autoclaving. An additional precaution is insulation of the back of each electrode. The electrodes may be covered with felt or they may be wrapped with flat gauze sponges that are tied in place. The felt or gauze should be moistened well with sodium chloride solution before the electrodes are applied to the heart. The defibrillator that has been described is illustrated in figure 2. Diagrams of two different, practical defibrillators are in figures 3 and 4.

RESUSCITATION KIT AND ITS ADJUNCTS

The instruments and drugs necessary or useful in cardiac resuscitation are listed in outline form.

I. Equipment required immediately for establishment of circulation and respiration
  A. Instruments for exposure of the heart; scalpel and self-retaining rib retractor
  B. Oxygen tank with bag and couplings that connect to a tight fitting face mask (preferably with airway). Laryngoscope, mouth gag, and intratracheal catheters and airways of different sizes may be needed
  C. Kreiselman apparatus should be available in all operating rooms if above equipment is not

II. Equipment required after circulation and respiration are established by artificial means
  A. Skin antiseptics and sterile towels, drapes, and gloves
  B. Instruments to control bleeding from chest wound when pulse and blood pressure have returned; hemostats, absorbable surgical sutures, forceps, and scissors
  C. Instruments to open pericardium if necessary to improve massage, verify presence or absence of ventricular fibrillation, or to permit application of electrodes directly to the epicardium; long forceps with teeth and long scissors
  D. Drugs
    1. Procaine hydrochloride, 1% solution
    2. Epinephrine, 1:5,000 solution
    3. Calcium chloride, 10% solution
    4. Procaine amide hydrochloride (Pronestyl)
    5. Atropine
  E. Syringes with needles
  F. Defibrillator unit including sterile electrodes covered with gauze or felt and connecting wires
  G. Instruments, suture material, and catheter to be used in closing the thoracotomy wound

The defibrillator and a sterile pack containing electrodes and connecting wires are the last items that must be available. Although a scalpel and rib spreader could be kept in readiness on each ward or in each minor operating room, it would not be practical to have a respirator or anesthesia machine and a defibrillator in every location in which it might be needed. It would seem wise to keep a complete resuscitation kit and adjunct equipment in readiness at some central point and to depend on mouth-to-mouth breathing to maintain respirations until the equipment can be brought to the patient.

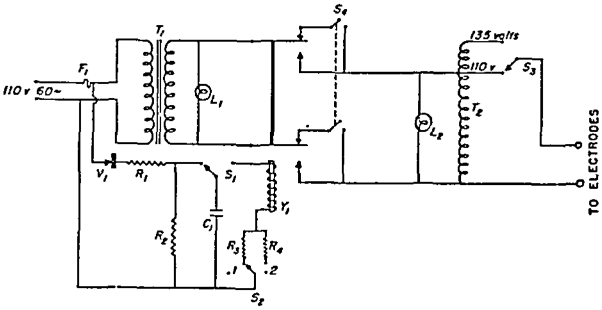

Fig. 4.—Defibrillator circuit devised by Mr. Richard Wexler. This circuit does not contain a vacuum tube.

SUMMARY

1. A technique of cardiac resuscitation is described in detail that includes (*a*) artificial respiration, (*b*) cardiac massage, (*c*) administration of fluids and blood intravenously if indicated, (*d*) administration of drugs, such as epinephrine, calcium chloride, procaine and procaine amide (Pronestyl) hydrochloride, and atropine, and (*e*) defibrillation by means of electric shock.

2. The defibrillator is described in detail. Construction of the defibrillator is discussed with regard to the effects of electric current on the heart. Circuit diagrams of defibrillators are included.

3. An outline of equipment required for cardiac resuscitation based on the technique described is presented. This list is designed to assist in preparation of the resuscitation kit and adjunct equipment.

Narcotics and Cancer.—The cancer patient presents a unique problem to the doctor who is called upon to decide when and what pain relieving drugs should be administered. . . . Since patients with cancer are always more or less mentally depressed and subject to periods of despondency, they are much more prone to develop dependency and habituation than are the usual surgical and medical patients. Since this is true, sedation and narcosis when needed as a temporary measure should, if possible, be accomplished by drugs having the minimal amount of habit forming qualities. Following surgery, if morphine or Pantopon must be used, their use should be discontinued as soon as possible. Where narcotics must be continued for a considerable period of time, codeine or Demerol may be satisfactorily substituted for morphine. This will make the discontinuance of narcosis much easier for both the patient and the doctor. Discomfort and mild pain during the course of treatment are best handled with non-narcotic drugs, such as aspirin, acetanilide, and barbiturates, either separately or in combination. Larger doses of aspirin than are usually given when repeated at regular intervals will prove more effective than is usually believed.—E. Callaway, M.D., Narcotics and Cancer, *Georgia Medical Association Journal,* May, 1953.

EVALUATION OF A THYROID PANEL

PRACTICAL APPLICATION OF SCINTILLATION COUNTER IN DIAGNOSIS OF DISEASES OF THE THYROID

T. F. Barrett, M.D., H. Peck, M.D., F. K. Bauer, M.D., R. L. Libby, Ph.D.
and
S. R. Jarrett, R.N., Los Angeles

Since I^{131}, the eight day, half-life isotope of iodine, became available on a large scale, its uptake by the thyroid gland has been used as a diagnostic test in the study of thyroid disorders. The thyroid uptake or diagnostic tracer study is generally afforded equal importance with the determination of serum protein-bound iodine (PBI), the basal metabolic rate, and the serum cholesterol level, the latter mainly in the diagnosis of hypothyroidism.

Recent improvements in instrumentation and particularly the development of the sensitive, gamma detecting scintillation counter [1] have made possible the use of tracer amounts as small as one microcurie of I^{131} for studying thyroid function. This amount is about one-hundreth of the dose that has been commonly used in the past and makes it possible, for the first time, to obtain repeat uptake values without exceeding a safe dosage level. This simple and reliable equipment, which is now commercially available,* makes possible the expeditious processing of a large number of patients in a thyroid diagnostic clinic. The uptake procedure outlined in this report can be carried out by a technician. Many other methods utilizing I^{131} have been suggested for determining thyroid function,[2] but many of these are too complex to be carried out in a simple and rapid manner in a thyroid clinic.

This report presents the results of a pilot study designed to evaluate the I^{131} tracer test (thyroid uptake) in a large Veterans Administration general medical and surgical hospital in which the patients are, for the most part, men. The hospital is located in an area in which goiter is not endemic.

METHODS

The instrumentation has already been described in detail.[3] Briefly, standardized doses of 2 μc of carrier-free I^{131} are prepared in capsule form.[4] The use of the dosage in capsule form has a number of advantages, particularly with respect to the ease of transportation from the standardization laboratory to the patient and the elimination of possible contamination through spillage. The patient is permitted a light breakfast and is given the I^{131} capsule with a small amount of tap water. Uptake studies are performed 6 and 24 hours after administration of the dose. The determination of the amount of I^{131} collected by the thyroid gland is carried out as follows: The patient is seated in a dental chair, and the chair is titled backward so that the patient's neck is in a horizontal position. The isthmus of the thyroid gland is located by measuring 5 cm. downward from the notch of the thyroid cartilage. The scintillation tube is then lowered over the thyroid area so that the center of the aluminum window of the tube is 5.6 cm. above the isthmus. Background counts are obtained over the knee and are subtracted from the thyroid counts to obtain the net count over the thyroid. This net count is expressed as a per cent of the administered dose count obtained under the same geometric conditions and represents the per cent uptake by the gland. A request slip should accompany the patient and should state the reason for which the test was requested, the tentative clinical diagnosis, and all medication that the patient has been receiving. Every effort is made to determine whether or not the patient has received desiccated thyroid, iodine containing medication, or iodized oils used in roentgenographic diagnosis, since these markedly modify the thyroid uptake.

It is emphasized that no pressure whatsoever was placed on the house staff for the referral of patients. At the time this pilot study was established, members of the house staff were encouraged to avail themselves of the facilities of the thyroid diagnostic clinic at their discretion. Patients in whom there was doubt as to the presence of thyroid dysfunction were referred. These included patients with symptoms such as nervousness, tiredness, and unexplained weight loss or weight gain. Also included were patients with heart disease of unexplained cause and brittle diabetics. Each of the house officers or attending physicians was thus a referring physician, and the situation was comparable to the relationship of private physician to a commercial laboratory. This method was felt to be vastly preferable to one in which only one physician examines all patients to be tested and the clinical impression depends on his index of suspicion and clinical acumen.[2b]

Basal metabolic rate, serum protein-bound iodine, and serum cholesterol determinations, according to the techniques of Barker and Humphrey [5] and Kingsley and Schaffert,[6] were performed at the same time or a few days after the I^{131} tracer test. The results obtained are analyzed with respect to: (1) accuracy of the tracer study as a routine clinical test to supplement the referring physician's clinical impression; (2) comparative diagnostic value of the tracer study and the other established thyroid function tests; (3) simplicity, practicability, and possible application of the tracer study in smaller hospitals to the exclusion of some of the other thyroid function tests.

Because of lack of space, some of the bibliographic footnotes have been omitted from THE JOURNAL and will appear in the authors' reprints.

MATERIAL

One hundred sixteen healthy control subjects were given an oral tracer dose of 2 μc of carrier-free I^{131}. The range of uptake values (7% to 23% in 6 hours and 12% to 35% in 24 hours) correlates well with those found by other groups of investigators[7] (table 1). As illustrated in table 1, 273 tests were performed on 213 patients. Of these 273 tracer studies, there were 195 normal tests and 78 abnormal tests, according to our criteria. The breakdown of these abnormal tests reveals that 17 were higher and 61 lower than the normal control values. The breakdown of the tests with values above normal (tables 2 and 3) shows that all but one can be explained on the basis of hyperthyroidism. The one patient (patient 17, table 3) with uptakes of 44% and 46% had normal protein-bound iodine and high serum cholesterol values. He suffered from hypertensive cardiovascular disease and had had a cerebral vascular accident. He was also in cardiac decompensation, on a low sodium diet, and receiving digitalis. Clinically, there was no evidence of hyperthyroidism. He had received potassium thiocyanate tablets two months prior to the test, but whether this accounts for the high uptake cannot be stated definitely. The rate of uptake in the same patient, as evidenced by the six hour determination, was normal. In this series of patients, no other high uptake that could not be explained was found.

TABLE 1.—*Results of Radioactive Iodine Uptake Tests*

	Men	Women	Total
Voluntary healthy controls	55	61	116
Number of patients	165	48	213
Number of tests on patients	211	62	273
Number of tests within normal range	147	48	195
Number of tests outside normal range (7 to 23% at 6 hr. 12 to 35% at 24 hr.)	64	14	78
Above normal	16	1	17
Below normal	48	13	61

The breakdown of low uptakes is given in tables 4 and 5. False low values due to "contamination" of the patient with thyroid medication or iodine containing compounds were more frequent than those due to hypothyroidism, adenomas, or thyroiditis. The factors responsible for uptake values below normal included thyroid medication (11 patients), iodine in Lugol's solution, potassium iodide, hydriodic acid, kelp, patent medicine tonics, and cough syrups (9 patients), dyes used in roentgenographic procedures (4 patients), and iodochlorohydroxyquinoline (Vioform) (1 patient). One patient with bromide intoxication had a low uptake and a high bromide level in the serum. Unfortunately, this patient failed to return for a repeat tracer study several weeks later. In several patients with congestive heart failure, it was observed that, although the total amount of I^{131} accumulated in the thyroid gland was within the normal range, the rate of uptake was slow (six hour determination). These are preliminary observations that are being studied further.

12	35	48	+ 8	8.4	143
13	50	58	+20	10.1	206
14	36	50	+ 8	9.8	138
15	24	52	+12	12.7	182
16	34	57	+37	7.9	151
17	(1) 21	44	.....	5	266
	(2) 22	46	.....	4	258

A number of uptake values were found to be at the lower range of normal, such as 10 to 12% in 24 hours. No satisfactory explanation can be offered for this finding in persons in whom the results of other laboratory tests were all within the normal range. Several such patients were referred to the thyroid clinic a few days after a surgical procedure. The lowered thyroid uptake might be explained on the basis of surgical trauma, such as that demonstrated by Blount and Hardy.[8] Whether other uptake values are due to nonspecific stress is mere speculation. It is emphasized, however, that these uptake values slightly lower than normal are not to be considered as being in the hypothyroid range. On the contrary, after examining these persons, it was found that the diagnosis made by the referring physician was possible hyperthyroidism, anxiety state, et cetera.

RESULTS

The following comparisons between the I^{131} tracer test, basal metabolic rate, serum protein-bound iodine, and serum cholesterol as indexes of thyroid function may be made as a result of this study.

TABLE 4.—*Causes of Low Radioactive Iodine Uptake*

Cause of Low Uptake	No. of Patients
Myxedema	10
Hypothyroidism after thyroidectomy or I^{131} therapy	4
Thyroiditis	5
Cortisone therapy	3
Thyroid adenoma, nontoxic	8
"False low"	28
Unexplained	3
	61

It is generally agreed that the basal metabolic rate correlates reasonably well with results of the tracer test in unequivocal cases of hyperthyroidism or hypothyroidism; however, its wide fluctuation in euthyroid persons limits its usefulness. Hyperthyroidism without apparent hypermetabolism has been described.[9] In such cases, the basal metabolic rate is normal, but the I^{131} uptake and the serum protein-bound iodine level are elevated. No such person was observed in our series. The tracer test as compared with determination of the basal metabolic rate has the advantage that the patient's cooperation is unnecessary. The tracer test is an outpatient test, since a period of rest is not necessary before the test. A combination of a high basal metabolic rate and a depressed uptake has been mentioned in factitious hyperthyroidism caused by secret thyroid medication.[10] No such case has come to our attention.

The serum cholesterol determination is valuable in patients with hypothyroidism but not in patients with hyperthyroidism.[2b]

The results of protein-bound iodine determination and of the tracer study compare very well in most instances. Our own experience confirms the observation that the combination of these two procedures is probably the best available laboratory tool for confirmation of the clinical impression of thyroid disease.[11] It can be seen from tables 1, 2, and 3 that, in all patients with hyperthyroidism, the two tests were diagnostic. It can be argued that only one of the two tests is necessary, but it is in the patient with suspected hypothyroidism that the two procedures are of great value. Low uptake and low protein-bound iodine level are normally found in hypothyroid persons. The uptake test is more sensitive than the determination of protein-bound iodine level in such cases, since, even in cases of full blown myxedema, a protein-bound iodine level of 4 μg per 100 cc. is not uncommon. If 5 to 7 μg per 100 cc. is the normal value, then it is readily apparent that the value of 4 μg per 100 cc. are not too helpful. The combination of a low uptake and a high level of protein-bound iodine indicates, in our experience at least, premedication with iodides; only the pattern of thyroiditis is similar. It has been our practice to elicit from the patient an exhaustive history with regard to the intake of compounds containing iodine. In almost every instance of low uptake and high protein-bound iodine level, this was found. Repeat uptake tests were performed in such instances, but at this time it cannot be stated how much time should elapse before such tests are accepted as truly diagnostic.

Table 5.—*Comparison of Laboratory Findings in Fourteen Patients with Abnormally Low I^{131} Uptakes*

Patient	Diagnosis	24 Hr. Uptake, %	Basal Metabolic Rate, %	Protein-Bound Iodine, μg per 100 Cc.	Cholesterol, Mg. per 100 Cc.
1	Pituitary myxedema	2	—28	6.8	384
2	Myxedema	0.6	—15	4	245
3	Postoperative myxedema	7.3	— 6	7.1	501
4	Myxedema	1	.....	5.1	349
5	Postoperative myxedema	2	—18	4.6	213
6	Postoperative myxedema	2	.....	...	...
7	Postoperative myxedema	6.3	—18	3.7	503
8	Hypothyroidism after I^{131} therapy	10	.....	4.2	340
9	Myxedema	1.5	—23	5.8	467
10	Myxedema	1	—35	3.6	536
11	Rheumatoid arthritis *	6	— 3	5	263
12	Dermatitis *	6	— 5	4.8	178
13	Dermatitis *	10	—13	4.7	116
14	Malignant hypertension, probable hypothyroidism	2	—34	7.1	205

* Patient receiving cortisone.

It is of interest to note the large number of patients who were taking thyroid medication. This depressed the uptake in almost every instance but usually did not raise the protein-bound iodine level significantly. In any patient who is receiving desiccated thyroid medication, it has been our practice to do the I^{131} uptake test and then repeat it three weeks later. Our data bear out the observations of Greer [12] who found that the uptake returns to normal in about three weeks after discontinuation of thyroid medication. Unpublished preliminary observations from this laboratory indicate, however, that the values obtained after three weeks may be abnormally high. Thus serial tracer studies made three weeks apart for several months indicate that a definite rebound phenomenon follows cessation of thyroid medication before the uptake values return to a normal pattern.

Attention is directed to the observation that of the 16 patients with hyperthyroidism only 6 diagnoses were clinically unequivocal. In five of the remaining cases, the primary diagnosis was heart failure of unexplained cause; in the other five, the diagnosis was suspected but confirmation was necessary before treatment could be instituted. All of the 16 persons with hyperthyroidism were treated and have improved, thus giving final proof of the accuracy of the laboratory tests. No patient with proved hyperthyroidism was found to have a normal or low uptake value.

The patients with full blown myxedema were all diagnosed without hesitation; the laboratory studies merely confirmed the clinical impression. Hypothyroidism was suspected in more persons in whom results of the tracer study turned out to be normal than in those with hyperthyroidism. The five patients with thyroiditis were all followed up after their disease had subsided and showed a normal uptake and protein-bound iodine value several weeks after the original tests. In three, the referring diagnosis was hyperthyroidism; only in the remaining two was thyroiditis considered. One patient with carcinoma of the thyroid gland had a normal uptake.

COMMENT

In our experience, the radioiodine thyroid uptake test is an accurate, sensitive, and practical laboratory aid in the diagnosis of thyroid disorders. The test is safe and rapid. It requires no special preparation of the patient, and the patient's undivided attention and cooperation are not necessary, as in the determination of the basal metabolic rate. A technician can do the test accurately, since the operation of the counting equipment is very simple. Since tracer doses of I^{131} can now be obtained commercially, close association with a radioisotope laboratory is not necessary. This is an advantage over the protein-bound iodine determination that must be done by specially trained technicians and with special equipment. In this study, one of us (S. R. J.) took charge of the thyroid diagnostic clinic because it was felt that only very careful examination of the patient's record would give information concerning premedication with iodized compounds, thyroid, and roentgenographic contrast mediums. This was eminently successful as every patient's record was examined, every patient was questioned with regard to premedication, and many cases of contamination were discovered to explain false low uptake values. As a routine procedure, however, it is felt that any technician can operate such a thyroid tracer laboratory under the supervision of a physician.

It should be emphasized that the I^{131} uptake test may not be the ideal thyroid function test and that it is not necessarily better than the determination of the protein-bound iodine level. It measures the avidity of the thyroid gland for iodine and is subject to the same errors as is the serum protein-bound iodine determination. These pitfalls are usually due to iodine or thyroid medication and should be attributed to "patient error" rather than to failure of the tests.

A great number of variants of the simple direct measurement of I^{131} over the thyroid gland have been described.[13] None of these methods fulfill the criteria for the ideal thyroid function test, and they are too complicated to be used as routine tests in a general hospital without close association of a radioisotope laboratory.

The 6 hour uptake and 24 hour uptake determinations are practical, since the 6 hour determination measures the rate of I^{131} accumulation by the thyroid gland and the 24 hour determination measures the approximate maximum concentration. The reasons for this have been described elsewhere.[14] It is the feeling in this laboratory that a 24 hour uptake test alone is sufficient for screening purposes but that much valuable information can be gained by obtaining an earlier determination such as one at 6 hours.

SUMMARY

The results of a pilot study of four thyroid function tests (basal metabolic rate, protein-bound iodine and serum cholesterol determinations, and radioactive tracer test) in a Veterans Administration hospital are reported. The radioactive iodine tracer test was performed with doses of 2 μc of I^{131}, administered in capsule form to control subjects and to patients suspected of having thyroid disorders. A scintillation counter was used to measure the uptake of I^{131} by the thyroid gland.

The radioactive iodine tracer test, using small doses of radioactive iodine and the scintillation counter, is a practical test and compares favorably with determination of the basal metabolic rate and protein-bound iodine and serum cholesterol levels. The combination of the protein-bound iodine test and the radioactive iodine tracer test is an excellent laboratory tool for confirmation of the clinical impression of thyroid disease. The radioactive iodine tracer test is sensitive and is probably the best available thyroid function test. The test can be performed by a trained technician with commercially available radioactive iodine and scintillation counter equipment.

The results of these four tests (basal metabolic rate, protein-bound iodine and serum cholesterol determinations, and radioactive iodine tracer test) in a series of unselected patients are presented and discussed.

THE ROLE OF EMOTIONS IN DERMATOSES

Gerald M. Frumess, M.D., Denver

The skin may reveal emotional states as eloquently as do the muscles of facial expression. Control of facial muscles may keep the visage inscrutable despite inner turmoil; but voluntary control is useless in suppressing the blush of embarrassment or the cold sweat of fear. Our daily conversation is replete with references to revelations of feelings on the integument. We speak of the face that becomes "purple with rage" or "white with fear." The person impervious to insult is referred to as "thick-skinned"; the sensitive one is "thin-skinned." Aware of danger, one's "hair stands on end"; he may "bristle with courage" or, frozen with fright, have cutis anserina ("goose flesh"). We refer to the "sweating-out" of an unpleasant situation. The expression to "sweat blood" finds its origin in purpuras and religious stigmas of hysterical origin.[1] The term "a blistering denunciation" is derived from the ability to produce blisters by hypnotic suggestion; the intensity of induced blisters may fluctuate with the emotional state of the subject.[2]

Sensory disturbances of the skin are also induced by emotions. Thus one "tingles" with expectation or is "tickled" by an amusing incident. Hostility may cause us to "itch for revenge." A repulsive sight makes our skin "crawl" or gives us the "creeps," the very sensations of patients afflicted with delusions of parasitosis. Fearful of a venture, we speak of getting "cold feet." We are "sitting on pins and needles" while awaiting an important decision—a preface to anal and genital pruritus. The symbolism expressed by excoriations has its parallel in the remark "stop picking on me."

The purpose of this paper is to examine the emotions responsible for changes in the skin; to describe the physical agencies through which they mediate these effects; and to discuss diseases of the skin that appear to have important emotional components.

EMOTIONAL COMPONENTS OF PSYCHOSOMATIC DERMATOSIS

English[3] describes eight common emotions, some of which are conspicuous in the personalities of patients with certain skin disorders. It is, therefore, of practical importance to investigate these emotions.

The need for love is one of humanity's greatest hungers.[3] If this hunger is unsatisfied, the resulting

---

Owing to lack of space, all of the bibliographic references have been omitted from The Journal and will be included only in the author's reprints.

frustration may lead to other unpleasant emotions. The person who believes himself unloved may resort to symbolic or perverted ways of obtaining affection. If these substitutes overflow into the autonomic nervous system, there is consequent itching and scratching. Thus certain skin diseases, especially localized neurodermatitis and anogenital pruritus, may be unconscious erotic substitutes for a lack of love.

Yaskin[4] states that anxiety is the central symptom of nearly all the psychoneuroses. One may be consciously aware of anxiety as feelings of fear and worry. If the causes of the anxiety are below the level of consciousness, however, an overflow into autonomic pathways commonly occurs, and bodily dysfunctions, including skin disorders, may result.

Anxiety may lead to hostility, which often is manifested aggressively as wholesome competitiveness, righteous wrath, or outbursts of anger. When hostility is repressed, however, the result is an irreconcilable conflict between desire for power and achievement and desire for affection and admiration. Horney[5] believes the conflict so established is the chief cause of the neuroses. Repressed hostility is the most frequently encountered trait in patients with disseminated neurodermatitis.[6]

Hostility, in turn, often results in feelings of guilt. The person experiencing guilt feels he cannot achieve the goals others or his own conscience have established for him. The result may be an attitude of self-sacrifice, creating tensions that overflow into the autonomic nervous system. Guilt may, on the other hand, dictate the need for self-punishment, with consequent excoriation and mutilation of the skin.

It is an unfortunate paradox that accepted social virtues, such as meticulousness, a ready sense of guilt, and restraint from manifestations of hostility and aggression, are often the cause of psychosomatic disease. It would seem that to be civilized, to be mannerly, to be conscientious, and to be ambitious, is to expose oneself to the danger of neuroses.

PHYSIOLOGICAL FACTORS IN EMOTIONS AND DERMATOSES

The emotions may cause changes in the skin by releasing certain substances at the autonomic nerve endings. These substances, in turn, may act synergistically with other biological factors to cause alterations in the skin. An understanding of these links between emotions and physical agents should reconcile the disputes between the organic and functional schools of etiology.

Two divisions of the autonomic nervous system are recognized: the sympathetic and the parasympathetic. Both divisions have physiological connections with the higher brain centers and may, therefore, be stimulated or inhibited by psychic changes. Parasympathetic fibers in general and sympathetic fibers to sweat glands liberate acetylcholine at their terminals.[7] Acetylcholine causes vasodilatation and secretory activity of the oil glands and sweat glands, (which are, however, of sympathetic innervation). Excitement, hostility, and embarrassment may stimulate these fibers, with subsequent flushing of the skin, oil secretion, and sensations of itching. Release of more acetylcholine causes further permeability of the blood vessels, whereupon whealing, or hives, may occur; still further permeability results in the escape of formed elements of the blood, with consequent purpura and even frank bleeding. Sympathetic fibers (except those to the sweat glands) liberate an epinephrine-like substance called sympathin.[7] Stimulation of this system is seen in reactions to fear and anxiety. Changes in the skin are pallor, coldness, sweating, cutis anserina, and crawling sensations. Some emotions produce a mixture of sympathetic and parasympathetic effects on the skin.

A neurotic person or a normal one under stress tends to have a set pattern of skin response to emotional stimuli. This pattern, if repeated often enough, may cause functional changes to advance to organic disease.[7]

There is a special relationship between allergy and the nervous system. This is explained biologically in the synergism of acetylcholine and histamine. A histamine-like substance is produced at the site of most allergic reactions. Reinforcement by release of acetylcholine of emotional origin at that site may cause histamine to produce a clinical allergic reaction when the concentration of histamine alone would be insufficient to do so.[8] This explains why so many persons experience allergic reactions only when they are emotionally disturbed.

Another important contribution to our knowledge of the interaction between emotional and physical factors is the recent concept of "internal sweating." When the sweat ducts become plugged and sweat continues to be secreted, the pressure within the ducts may rise to 240 mm. Hg.[9] There are over 2 million sweat glands in the human skin. In areas where the glands are occluded by scales or inflammation, it is understandable that retained sweat feels like the pricking and stinging of countless hypodermic injections. Since sweating may be caused by emotional stress, the already inflamed skin rapidly responds to "internal sweating" by a flare-up. These outbursts can sometimes be forestalled by the use of anticholinergic drugs, such as methantheline (Banthine) bromide and diphenmethanil (Prantal) methylsulfate, which inhibit sweating. With sweat retention there may also be retention of allergens that would normally be excreted with the sweat.[9] These allergens, dammed back and under greatly increased pressure, may cause allergic reactions that occur only if sweat is secreted and the sweat ducts are plugged.

ROLE OF EMOTIONS IN SPECIFIC DISEASES

Emotional factors affect two skin diseases of proved organic etiology: warts (verrucae) and fever blisters. The common wart is a benign tumor caused by tissue response to a virus infection. The power of suggestion in curing warts has been known for centuries. Witch doctors and medicine men often gained their reputations by the successful employment of necromancy in treating warts. Mark Twain's Tom Sawyer and Huckleberry Finn effected cures by resorting to nocturnal sorcery. It is ethical practice today to use suggestion in treating warts.

Recurrent herpes simplex as manifested by fever blisters or "cold sores" is another disease of proved virus etiology. The latent virus, carried by most adults, is usually activated by upper respiratory tract infections, fever, upset stomach, and other identifiable factors. A group of 10 patients with recurrent herpes simplex that had no such correlation to organic factors was studied by Blank and Brody.[10] Nine of the ten patients showed an amazing uniformity in psychological patterns in that they were immature, passive, dependent, and highly suggestible. Hostility was recognized in conflict with their desire to please. Brief psychiatric treatment was usually sufficient to control the attacks of herpes simplex, at least during the period of active psychotherapy. Many patients with recurrent herpes simplex recognize the relationship between emotional disturbances and attacks of this disease.

Blushing, or flushing, is the commonest external manifestation of parasympathetic stimulation. English [3] states that the blush symbolizes inner excitement. A desire to conceal this excitement and fear of its exposure provide psychic stimuli resulting in the blush. Seitz [11] states that blushing is a reaction to guilt and that a consequence of blushing is pruritus and scratching. Common skin disorders such as rosacea, urticaria of psychogenic origin, eczema of the flush areas, solar dermatitis, and lupus erythematosus occur when persons with the flush mechanism are subjected to certain organic disturbances.

Rosacea occurs in persons with the blush tendency who are also subject to gastrointestinal disturbances and menopausal disorders.[12] These patients are quiet, reserved, serious-minded, and bashful.[13] They rarely react aggressively to attack but, rather, become obstinate and sullen. A high level of self-esteem causes them to suppress feelings of guilt and shame. Treatment of rosacea requires that this personality pattern be corrected, as well as the gastrointestinal disorder and the skin blemishes.

Another consequence of the blush mechanism is seen in patients with urticaria of psychogenic origin. An emotional factor is present in most cases of urticaria.[14] Clinical and psychoanalytic studies performed on patients in whom biological causes of urticaria have been satisfactorily excluded delineate personality types that have certain common characteristics.[15] All seem to have intense longings for achievement; they are driving, keyed-up persons, intent on a goal. They often consider themselves wronged or injured, usually by someone in a fairly close family relationship, and regard the situation as one that precludes any personal action.[16] A conflict between the desire for power and the desire for approval results in the vasomotor components of urticarias. Reference has been made to synergism between histamine produced on an allergic basis and acetylcholine produced on an emotional one. This explains the frequent observations that a person can eat tomatoes with no resultant hives except at times when he is emotionally disturbed. Since tension in hard-driving people who long for achievement can usually be lowered by psychotherapy, this method is an important aid in the management of urticaria with psychogenic elements.

Atopic eczema of infancy and childhood is a challenge to several specialties. Many afflicted children carry hereditary allergies, and this factor must be considered in treatment. Carefully directed topical therapy often alleviates the symptoms. A psychiatric approach to the parent has recently afforded a further means of managing this disease. Williams [17] studied atopic dermatitis in children from the standpoint of the maternal rejection factor. Of 33 children examined, 31 manifested symptoms of maternal rejection according to accepted criteria.[18] In the other two cases the mothers demonstrated attitudes suggesting rejection of the child. Therapy was directed mainly toward correction of the mother's behavior toward the child. Favorable results in this series exceeded those achieved by topical applications and conventional methods of therapy in allergy. In childhood eczema there is a constant "battle of the wits" between child and parent, in the course of which the child discovers that his most potent weapon is an orgy of scratching. This weapon is used in retaliation against persons and situations that threaten his sense of security. I have noted the prevalence of eczema in adopted children. While consciously "wanted" by their parents, they sense the presence of unconscious rejection by the mother, to whom the adopted child is, at best, a substitute for the one she could not conceive and whose imagined qualities the foster child fails to fulfill. A psychiatric approach to parents in the therapy of infantile atopic eczema must be accepted as an aid to conventional methods of treatment.

Adult patients with neurodermatitis, or atopic eczema, have certain traits in common with those exhibited by children with eczema. There is a significant frequency of personal and family atopy. Almost invariably anxiety exists, expressed as hostility. This may still have as its target the mother or a mother figure.[19] Unlike the eczematous child, however, the adult with eczema suppresses resentments and turns them inward. This trait has been demonstrated by clinical studies,[6] Rorschach patterns,[20] and the use of other projective tests.[21] Resentment may be disguised as superficial compliance; therefore the patient may appear to be complaisant and acquiescent up to the very moment when he rejects his physician in favor of another therapist. The hostility, on the other hand, may be more overt. In such cases the physician dreads each visit of the patient, with his scepticism toward every proposed remedy. The person with neurodermatitis is very meticulous in his habits. He may produce at each office visit an itemized list of questions to ask the physician. The patient is usually above average in intelligence and is aware that his ambitions surpass his talents. Frustration is the inevitable consequence. He has, literally at his fingernails, a means of emancipation from situations that threaten his adequacy: he scratches.

Most patients with disseminated neurodermatitis benefit from judicious psychotherapy. The ideal therapist would combine the talents of a competent dermatologist, an alert allergist, and a prudent psychiatrist. Combined medical and psychological therapy by one physician is most frequently indicated in cutaneous conditions with emotional aspects.[22] Haphazard psychological probing in the presence of severe or long-standing neuroses, however, is dangerous. It may result in the breaking up of homes, suicide attempts, development of frank perversions, or acute psychotic reactions. These possibilities should be anticipated, and the patient with deep-seated neuroses should be referred for skilled psychiatric treatment. If such care is unavailable, the physician should do the best he can with medical treatment alone.

Seitz and Gorman [23] assert that the dermatologist can practice psychotherapy if he possesses certain qualifications. He must enjoy helping people, be able to sit quietly and listen comfortably, refrain from displaying restlessness, and possess some training in dynamic psychotherapy. The patient must be one whose skin disorder is not too long-standing; his past history should be one of relatively good adjustment; and his emotional conflicts should be of recent origin. Therapy may safely include supportive methods that reinforce the patient's feelings of adequacy and security, promote harmony, and provide him opportunity to discuss his conflicts.

Localized neurodermatitis, or lichen simplex chronicus, usually appears as isolated patches of thickened skin, with intense itching. Severe scratching or overtreatment may produce acute flare-ups with edema and exudation. Common sites of involvement are the nape of the neck, the pretibial areas, the scrotum, the vulva, and the anal region. Careful search for organic causes must be made before the diagnosis of essential pruritus or neurodermatitis of the anogenital areas becomes tenable. Frequently an organic factor of chemical, mechanical, infectious, or allergic nature starts the process, though it may continue as a purely psychogenic itch, with lichenification or thickening a result of scratching. In either event, the scratch habit becomes so inveterate that if topical and physical agents prove incapable of breaking this vicious cycle of itching, scratching, and lichenification, then psychotherapy must be used. Localized neurodermatitis, while usually not a serious malady, may be the somatic expression of deep-seated emotional disturbance. It may symbolize an erotic substitute for lack of love or an immature means of securing genital pleasure; or the scratching may emanate from a sense of guilt and a consequent need for self-punishment in the form of excoriation. The personality type of these patients does not lend itself to superficial psychological exploration; if psychotherapy is necessary, it should be conducted by one well trained in its methods.

Eczema of the hands is a complex, often disabling disease of diverse etiology. Since the palmar surfaces are especially prone to exhibit emotional sweating, this factor is important in all types of hand eczemas, whether of psychogenic, organic, or allergic etiology. Maceration of the skin by sweat renders it more pervious to chemical irritants and contact allergens. More important is the sweat-retention factor previously mentioned, in which plugging of the sweat ducts occurs with subsequent "internal sweating." This may be the primary cause of dyshidrotic eruptions, and may secondarily intensify hand eczemas of all types.

Frequent references have been made to the role of the emotions in other dermatoses, such as psoriasis,[24] seborrheic dermatitis,[25] lichen planus, alopecia areata,[26] and dermatitis herpetiformis and to the psychological consequences of disfiguring skin diseases such as acne vulgaris and lupus erythematosus.[27]

A few diseases of purely functional nature are encountered by the dermatologist. Delusion of parasitosis [28] is a manifestation of a deep-seated psychosis. In the course of this disease the patient brings rolled-up bits of tissues and crusts he has removed from his skin, asking the physician to identify these "worms" or "bugs" that are crawling on or in him. Phobias commonly encountered by the dermatologist are fear of syphilis and fear of cancer. Klauder [29] believes that burning tongue, for instance, is invariably the expression of fear of cancer, often aroused by indiscreet remarks of a physician. Neurotic excoriations and self-inflicted mutilations, whether imposed upon or independent of coexisting skin disease, may result from guilt feelings and a strong need to disfigure or to cause pain and call attention to oneself in some perverse way; or it may be a conscious means of malingering to secure sympathy or compensation. These functional diseases represent psychiatric problems and are amongst the most severe and intractable psychiatric conditions.

SUMMARY

Commonly encountered emotions such as insecurity, anxiety, hostility, and guilt may cause stimulation of the autonomic nervous system, leading to flushing, sweating, itching, and excoriating. Physical agents through which emotions mediate these effects are acetylcholine released at parasympathetic nerve fiber endings; sympathin produced by sympathetic stimulation; synergism between acetylcholine and histamine; and the mechanical and allergic effects of sweat retained under pressure.

Several skin disorders believed to be of emotional origin exhibit fairly characteristic personality patterns. An effort has been made to relate the clinical entity to the emotional pattern in herpes simplex, rosacea, urticaria, childhood eczema, adult neurodermatitis, and localized neurodermatitis. In most such cases it is desirable that one physician supervise both the somatic and psychic aspects of therapy. Functional dermatoses such as delutions of parasitosis, syphilophobia, dermatitis factitia and neurotic excoriations result from deep-seated neuroses or psychoses and should be referred to the psychiatrist for treatment.

2200 East 18th Ave.

The Work of a Ship Surgeon.—People are always liable to sudden illness. Cases of acute appendicitis occur now and then in . . . places ideal from a health point of view. The same holds good in the case of ships, however modern and hygienic; indeed, even more so, considering the sudden changes of climate to which all on board are subject during a voyage of any duration, also the dietetic risks taken ashore at various ports of call. To this must be added: (1) the almost invariable presence on board, among the passengers, of cases of chronic illness, e. g., diabetes mellitus, gout, arthritis; (2) the presence on board of the crew, who are "super-liable" to accidents, right round the clock. Passengers seem strangely oblivious of the latter; they mostly have the idea that the doctor is on board primarily in their interests, whereas, . . . in strict legality, there is no onus on the shipowner to provide a surgeon for passengers per se—except in respect of an old-standing legal requirement whereby a doctor has to be provided when 50 or more emigrant or third-class passengers are on board. . . . There is a vast difference between the small "passenger-cargo" ship with just over 100 "souls on board" and the large modern passenger liner. The two Cunarder "Queens" have each, when full, a total complement of round about 5,000 persons on board, to meet the medical needs of whom two surgeons, three nursing sisters, and six hospital or surgery attendants are required. . . . In these large ships, with their relatively huge complements, any sort of emergency may arise at any hour, from which it follows that the surgeons on board have to be "universal" specialists, of a sort able to give at least first aid in the various specialties.—J. S. Meighan, M.D., The Ship-Surgeon's Life, *Practitioner,* May, 1953.

SERUM HEPATITIS FROM POOLED IRRADIATED DRIED PLASMA

William P. Murphy Jr., M.D.
and
William G. Workman, M.D., Bethesda, Md.

An understanding of the relationship between the occurrence of homologous serum hepatitis and the transfusion of pooled dried human plasma irradiated with ultraviolet light is necessary in order to evaluate the usefulness of the large volume of dried plasma now being manufactured. Early reports [1] indicated that the etiological agent of homologous serum hepatitis is destroyed by ultraviolet irradiation. More recent reports [2] have indicated that the methods of irradiation are not always adequate. The present study was conducted to determine further the role of irradiated dried plasma in the transmission of homologous serum hepatitis.

The plasma used in this study consisted of official test samples submitted by seven licensed processors to the Laboratory of Biologics Control of the National Microbiological Institute for evaluation before release of the material. Samples from each processor are tested for sterility, freedom from pyrogens, hemoglobin content, and solubility and must meet minimum requirements before release for human transfusion. All of the samples used represented lots of plasma manufactured for the armed forces. A record is kept in the Laboratory of Biologics Control of the clinical use of many of these lots of plasma, making possible the patient follow-ups reported here. Patients who received plasma prepared by these seven processors between Jan. 1, 1951, and April 1, 1952, are included. Clinical use was reported by a responsible physician in each of seven hospitals.

The records of 464 patients were investigated, and, of these, 180 could be followed up well enough to be included in the study. The other 284 patients investigated were excluded from the series for the main reasons of: early death (176), incomplete or missing hospital records (35), and inability to locate the patient (69). Since pooled plasma does not have to be typed and is readily available, it was used to treat patients in critical condition, as the result of either chronic disease or acute injury. Early death from these causes accounted for the majority of exclusions. The patients included had received the plasma at least 150 days prior to follow-up examination. No effort was made to determine whether or not human blood products other than plasma and whole blood were used. When possible, patients were interviewed in order to determine the presence of serum hepatitis. They were not asked leading questions, but were encouraged to relate their symptoms if any had occurred. They were questioned about general health, specific diseases, ability to work, contacts, malaise, anorexia, nausea and vomiting, abdominal tenderness, and pruritus, as well as jaundice. A patient who could not be interviewed because he had left the locality or had died was included in the series only if he had been examined by a physician at least once every two months from the second to the sixth month after receiving the plasma. Contact with private patients was made by the attending physician, and the information was accepted in writing.

The 180 patients in this study received a total of 403 units of plasma containing 600 cc. each. Sixty-four patients (35.5%) received plasma alone, while the rest (64.5%) received whole blood as well. Twenty-three patients, or 12.8% of the 180, had a history of signs and symptoms of serum hepatitis. Of the 64 patients who received only plasma, 6 (9.3%) later had hepatitis. No patients were included who did not show jaundice. Two additional cases of jaundice were found in which a history of exposure to infectious hepatitis eliminated the diagnosis of definite serum hepatitis. Two other cases of jaundice were considered to be secondary to biliary obstruction. Twenty of the 23 cases were diagnosed on readmission of the patients to the hospital, and the other 3 were diagnosed from the history given on personal interview. Table 1 shows the number of patients studied at each hospital and the incidence of hepatitis found.

TABLE 1.—*Incidence of Serum Hepatitis Among Patients Receiving Irradiated Plasma*

Hospital	No. of Patients Studied	Cases of Hepatitis	Incidence of Hepatitis, %	Deaths
1	33	2	6.0	1
2	27	2	7.4	..
3 *	..	..	...	..
4	17	5	29.4	2
5	60	8	13.3	2
6	30	3	10.0	1
7	13	3	23.0	1
Total	180	23	12.8	7

* In hospital 3, the 12 patients who received the plasma were not available for the study.

In the 23 cases of hepatitis presumably resulting from the administration of whole blood or irradiated plasma, there were 7 (30.5%) deaths apparently due to hepatitis. There was one other death among the persons who contracted the disease, but this was probably a direct result of the primary disease, with the hepatitis as a contributing factor. Plasma from each of the seven processors was involved in one or more cases of hepatitis. Table 2 shows the manufacturers and amounts of plasma given in the 23 cases of hepatitis. Dried plasma prepared from fresh

blood as well as reprocessed * plasma was involved, and there was no apparent relation between the number of cases and type of plasma, nor was a relation found between the number of cases of hepatitis and the method of ultraviolet irradiation.

COMMENT

The attack rate of serum hepatitis resulting from the injection of infected material is estimated by Paine and Janeway[3] as being about 40%. This incidence agrees with that obtained by Murray and others[4] in experimentally induced hepatitis. The fact that the present study shows a lower rate (12.8%) is probably the result of several factors. Perhaps most important is the indication that ultraviolet irradiation is effective to some degree, although not completely. Furthermore, in view of the fact that other studies of this disease[5] have revealed a definite incidence of nonicteric cases of serum hepatitis, it seems likely that there were additional undiagnosed cases and that the true incidence of the disease was higher than reported here. Studies showing an incidence of nonicteric hepatitis have, however, been those in which laboratory studies were possible, which was not the case in this series.

Many patients receiving plasma also receive whole blood, and nearly all receive many skin punctures by instruments that may be ineffectively sterilized. Since reports indicate that as little as 0.0001 to 0.00001 cc. of infected material can transmit the disease,[6] the origin of the infection may often remain questionable. Although a skin test for infectious hepatitis has been described,[7] it was not utilized in this study. Since only a positive history of contact combined with short incubation distinguishes infectious hepatitis from serum hepatitis, this similar disease serves to confuse the issue further. A study to determine the occurrence of serum hepatitis can be absolute only in a negative way; that is, if no cases of serum hepatitis can be elicited in a significant number of patients, then the plasma has not been infective. On the other hand, evidence of cases occurring may be of value if the total incidence is significantly higher than the incidence of endemic infectious hepatitis and whole blood transfusion hepatitis.

The occurrence of serum hepatitis as the result of the transfusion of whole blood is generally considered to be less than 0.5%.[8] The incidence of infectious hepatitis in one of the three cities in which this study was done was 0.02% per year; 198 cases were reported in 1951 in a population of 985,000. Of the 77 patients who had received plasma (and in some instances whole blood as well) in this city, 13 (16.7%) later had jaundice. The percentage of jaundice found in this group of patients is then far higher than the probable combined occurrence of infectious hepatitis and hepatitis from blood transfusions.

The seven deaths were about evenly distributed among patients in the fourth to eighth decades of life (fig. 1). In the third decade, which is well represented, no deaths occurred. Although the number was too small to be significant, the mortality rate was compatible with other reported studies.[9]

The findings in this study indicate that ultraviolet irradiation of pooled plasma by method of large-scale production is not wholly effective for complete destruction of the agent of homologous serum hepatitis. Transfusion of pooled dried plasma, even though irradiated, involves a calculated risk that should be considered carefully in relation to the need of the patient for this therapeutic agent.

---

* Reprocessed plasma is that which has been processed to the final stage once and is then reconstituted, pooled, clarified, irradiated, dispensed into the final container, dried, and finally tested. The reprocessed plasma referred to here had not been irradiated during the original processing, and was, therefore, reprocessed in order to expose it to ultraviolet irradiation.

Incidence of hepatitis and deaths by age groups.

SUMMARY AND CONCLUSIONS

Four hundred and sixty-four records of patients who had received pooled. dried irradiated human plasma 150 or more days previously were investigated. The records of 180 patients were found adequate to warrant a study of the occurrence of serum hepatitis as a result of the plasma transfusion. Twenty-three or 12.8% of the 180 patients had signs and symptoms of serum hepatitis. Seven or 30.5% had died as a direct result of the disease or a combination of their original disease and the hepatitis. Of 64 patients who had received only plasma and no whole blood, 6 (9.3%) had hepatitis. The occurrence of a 12.8% incidence of hepatitis is considered significantly higher than that of hepatitis as the result of blood transfusion alone (0.5%) or the incidence of infectious hepatitis (0.02%). The findings indicate that the methods now used for the irradiation of pooled plasma in large-scale production are not wholly effective in complete destruction of the agent of homologous serum hepatitis.

Pooled human plasma, untreated, has been a frequent cause of serum hepatitis. Blood from one donor carrying the virus can make a whole pool infectious. Obviously the likelihood of plasma being infected varies with the number of donors making up the pool. Plasma from a large pool is more frequently infected than plasma from a small pool. The probability of contracting serum hepatitis from a whole blood transfusion is extremely small. Paine and Janeway[1] have analyzed reports on this subject.

Exposing plasma to ultraviolet light seemed to obviate this hazard. Known icterogenic serum so treated has been given in small quantities to volunteers without causing hepatitis.[2] MacCallum,[3] on the other hand, used a different technique of irradiation that failed to prevent the transmission of hepatitis. Irradiation of plasma has been required by the National Institutes of Health since April, 1949, as a prerequisite to licensing manufacturers.

That irradiation does not always inactivate the virus was shown by James, Korns, and Wright[4] who reported the occurrence of 12 cases of serum hepatitis among 20 recipients of one lot of irradiated plasma. Of course this outbreak could have been due to faulty irradiation of the plasma involved, rather than to the inefficacy of irradiation as a means of inactivating hepatitis virus. There have been other reports[5] attributing serum hepatitis to irradiated plasma, but this apparent association could have been coincidental rather than causal. To pursue this problem further, a series of patients who received irradiated plasma from several sources was studied to determine whether irradiated plasma, as it is routinely prepared for commercial distribution, carries with it a definite risk of producing serum hepatitis.

MATERIALS AND METHODS

All patients receiving irradiated plasma during the period from late 1949 to early 1952 in three upstate New York hospitals were studied. The hospitals were chosen because they had accurate and generally complete records of the lot numbers of the plasma used. Two of the hospitals obtained their plasma from a single commercial source (plasma B), and the third used plasma from the same as well as another commercial source (plasma A). The pools ranged in size from 51 to 256 donors, averaging 114, for plasma B and from 53 to 178 donors, averaging 150 for plasma A. The plasma was processed in accordance with the requirements of the National Institutes of Health. Since many of the patients received whole blood in addition and since nearly all hospitalized patients received some sort of needle injection during their stay, it was necessary to evaluate these possible sources of infection. Furthermore, subsequent jaundice in these patients might have been due to naturally acquired infectious hepatitis. In order to assess these factors, a control group was studied. Controls for the recipients of plasma plus whole blood were chosen from the hospital blood bank list of whole blood recipients. Controls for the plasma recipients who did not receive whole blood were chosen from a list of hospital admissions. These persons were selected without prior knowledge of the outcome of their illness. The first patient listed who was of the same sex and roughly the same age as the plasma recipient and who was a patient in the hospital at the same time was chosen as the matched control. Most of each group were surgical patients. None of those in whom hepatitis later developed had been given human thrombin, a reported source of serum hepatitis.[6]

* Plasma is designated A or B, depending on the commercial source; arabic numerals represent different lots of plasma.

Many plasma recipients died shortly after transfusion and were not considered further. Of the 149 plasma recipients remaining for study, 11 were lost from observation, one was excluded because he had hepatitis at the time of the plasma transfusion, and one was excluded because she had been given a variety of blood products over a period of years. Five patients were excluded because they did not survive the possible incubation period of serum hepatitis that, for the purpose of the investigation, was defined as one to six months and because they did not have the full opportunity to acquire serum hepatitis. These five died, without evidence of hepatitis, at intervals ranging from two to five months after the plasma transfusion; thus, 131 plasma recipients were included in the study group. The control group was restricted, in the same way, to those who survived the six month period following the last plasma transfusion given to the matched plasma recipient. If a control died from a cause other than hepatitis during this six month period, another was selected to replace him; thus, the control group consisted of 131 patients.

Efforts to detect hepatitis in these groups consisted of a review of the hospital records, a letter of inquiry to the attending physician, and a visit by the epidemiologist to the patient. Six of the 131 in the study group, and six of the 131 controls had died by the time the study was initiated, although they had all lived at least six months after the last plasma transfusion. In these instances, their families were interviewed. The purpose of the visit was to ascertain whether the plasma recipient, or the control, had suffered from hepatitis or an illness suggestive of hepatitis that was unknown to the hospital or to the physician in attendance at the time of hospitalization. Home visits were made to both groups of patients from

No blood...........	18	0	10	0	12	0	40	0
Total............	134	7	40	0	88	4	262	11

Overt jaundice was chosen by definition as an essential criterion of hepatitis because the diagnosis of hepatitis without icterus, if not made at the time of illness, could hardly be established later.

RESULTS

In the 131 recipients of plasma studied, hepatitis, as defined above, developed in 10, or 7.6%. In contrast, in the 131 controls, hepatitis developed in only one, or 0.8%. All cases of hepatitis had been previously recognized as such by the attending physician. Review of the clinical and laboratory details by the epidemiologist served to confirm the impression that the illnesses were typical of icteric infectious or serum hepatitis. None of the patients had a previous history of hepatitis. None had a history of biliary disease except one (case 8, table 1). No blood donor gave blood to more than one of these persons with hepatitis. Other pertinent details are listed in table 1. There were no deaths caused by hepatitis. The incubation period ranged from 69 to 117 days except in one instance (case 11, table 1) in which it could have been any interval from 25 to 61 days. The day when jaundice was first noted was considered the day of onset.

Hepatitis occurred in patients from hospitals A and C but not from hospital B (table 2); however, this may be explained by the small number of recipients included in the study from hospital B. Six of the 10 hepatitis cases were among 91 patients who received plasma plus whole blood, and the other 4 were among the 40 patients who received plasma only. The control in whom hepatitis developed had received whole blood. Table 3 presents the incidence of hepatitis in patient and control populations by age groups. The absence of hepatitis in the group under 20 years of age may be a chance observation; on the other hand, it is in agreement with the reported experience of others [7] and may be a reflection of relative resistance or of a smaller proportion of icteric disease in this age group.

The 40 patients given plasma but not whole blood each received an average of 1.5 units of plasma. Some of the patients received more than one unit of the same lot. Since minute amounts of plasma can transmit serum hepatitis, multiple units from the same pool of donors may represent little or no greater risk than one unit; on the other hand, it is necessary to consider how many different lots of plasma were received by the average patient. This numbered 1.2.

Each of the 91 patients given plasma and whole blood received an average of 4.5 units of whole blood (totaling 410 units) and 2.4 units of plasma, of which 1.5 were from different lots. The 91 matched controls each received an average of 2.4 units of whole blood (totaling 215 units). Although most of each group were surgical patients, a greater proportion of the controls consisted of patients undergoing elective surgery. This may explain the reason for which they were given less whole blood. This difference in the number of whole blood transfusions does not account for the fact that there were 6 cases of hepatitis among the 91 plasma and blood recipients and only one case in the 91 controls receiving whole blood.

The reports analyzed by Paine and Janeway [1] indicate that about 0.2% of whole blood transfusions cause hepatitis with jaundice. The highest rate (0.35%) was that found by Lehane and co-workers.[8] Even with this high rate of 0.35% one would expect only 1.4 cases in the 91 plasma and whole blood recipients and 0.8 cases in the 91 matched controls. The true incidence of hepatitis with icterus in recipients of whole blood is probably less than 0.35%. There was no correlation between the number of whole blood transfusions per patient and subequent development of serum hepatitis (table 4).

[8] Lehane, D.; Kwantes, C. M. S.; Upward, M. G., and Thomson, D. R.: Homologous Serum Jaundice, Brit. M. J. 2: 572-574 (Sept. 10) 1949.

Paine and Janeway[1] estimated, from various reports, the carrier rate of serum hepatitis in the population of blood donors and the percentage of recipients of icterogenic material in whom hepatitis with icterus developed. We did not attempt to use their estimates for the purpose of calculating the number of cases of hepatitis that might have been expected had the plasma not been irradiated. There are too many variables, not the least of which is the actual prevalence of carriers in the donor population, to permit reliable conclusions.

TABLE 4.—*Whole Blood Transfusions Given to Plasma Recipients and Controls Aged Twenty or Over*

Number of Whole Blood Transfusions	Recipients	Cases of Serum Hepatitis No.	Cases of Serum Hepatitis %
0	62	4	6
1	62	2	3
2 to 3	56	3	5
4 or more	45	2	4
Total	225	11	5

It was planned to evaluate the icterogenicity of each lot of plasma; however, of the 56 plasma lots studied, very few had been given to more than a handful of patients. For example, 25 of these lots were given to only one patient each. Nevertheless, table 1 shows that in plasma recipients in whom serum hepatitis developed, a minimum of seven lots were involved (if all 10 cases were acquired through this mechanism). Attempts were made to study the experience elsewhere in the United States with other units of these same seven lots of plasma, but barriers to adequate follow-up prevented further investigation.

It might be suggested that the discovered serum hepatitis was related only to plasma processed early in the experience with this technique and that later improvements in the irradiation procedure allowed the production of virus-free plasma. In reality, however, hepatitis occurred in patients receiving plasma irradiated in 1949, 1950, and 1951 (table 5). The relative icterogenicity of plasma irradiated in different years cannot be properly assessed because of the small numbers of recipients and cases involved.

TABLE 5.—*Cases of Hepatitis Occurring One to Six Months After Transfusion Among Recipients of Irradiated Plasma by Year of Irradiation*

Year of Irradiation	Average Number Different Lots per Recipient	Number of Recipients *	Cases † Number	Cases † Attack Rate, %
1949	1.3	56	7	12.5
1950	1.3	56	1	1.8
1951	1.3	18	2	11.1
Unknown	...	8	0	0.0

* Five persons receiving plasma irradiated in 1949 and 1950 and two persons receiving plasma irradiated in 1950 and 1951 were included in both years.

† Of the four cases of hepatitis in patients who received plasma but not whole blood, three occurred in recipients of plasma irradiated in 1949 and one in recipient of plasma irradiated in 1951.

COMMENT

The purpose of this study was to learn if administration of irradiated plasma, as it is routinely prepared for commercial distribution, carries with it a definite risk of producing serum hepatitis. The tenfold difference, observed in this study, in the attack rates of hepatitis in recipients of irradiated plasma compared with the attack rates in matched controls, suggests strongly that irradiation did little to reduce the risk of serum hepatitis. It seems unlikely that any of the cases observed represented naturally acquired infectious hepatitis, since this disease was not known to be present in the environment of the patients either in or out of the hospital. The scattering of onset dates over a three year period and the observed interval, ranging from 61 to 117 days, between receipt of plasma and onset of jaundice are more suggestive of serum hepatitis. No secondary cases among the family and other contacts developed, as might have been expected had the disease been infectious hepatitis. The fairly close similarity between plasma recipients and matched controls, except for the one item of plasma administration, argues strongly against the possibility that other modes of transmission, such as needles, syringes, or surgical instruments, played a significant role. All three of the hospitals followed the practice of autoclaving syringes and needles after each use. As was stated earlier, human thrombin[6] was not administered to any of the patients in whom serum hepatitis developed.

Obviously the series is too small to allow exact definition of the risk from irradiated plasma, and one may draw conclusions only with regard to the particular lots studied. Since probably at least 9 of 131 plasma recipients acquired serum hepatitis from the plasma and since each had received an average of 1.3 units from different lots, the risk of contracting the disease from a single unit may be calculated as 5%. This estimate does not take into account the 11 recipients who were lost and the 7 who were excluded from the study, although, it indicates an appreciable risk of about 4.5% as described by Brightman and Korns[7] in their study of dried, pooled, unirradiated plasma. Since it is not known how many cases of serum hepatitis would have occurred had the plasma not been irradiated, it is not possible to state categorically that irradiation failed to reduce the icterogenicity of the particular lots studied. These findings raise serious doubts, however, as to the value of this procedure. The question of whether the techniques of irradiation can be or have been improved to uniformly destroy hepatitis virus is not within the province of this report.

SUMMARY AND CONCLUSIONS

One hundred thirty-one recipients of irradiated plasma and 131 matched controls from three hospitals were studied in order to determine the incidence of hepatitis during the period one to six months after plasma administration. Ten cases (7.6%) of acute hepatitis occurred in the group receiving the plasma, and one case (0.8%) occurred among the controls. It is believed that the cases in the group receiving plasma can be attributed to that source and that irradiation of the plasma lots studied failed to prevent or to significantly reduce the transmission of serum hepatitis.

CLINICAL NOTES

SPONTANEOUS PERFORATION OF SIGMOID COLON IN PRESENCE OF DIVERTICULOSIS

REPORT OF TWO CASES WITHOUT EVIDENCE OF INFLAMED DIVERTICULA

William T. Fitts Jr., M.D.
and
Lewis D. Anderson, M.D., Philadelphia

It is widely recognized that perforation of the sigmoid colon leading to abscess formation or spreading peritonitis is a common complication of sigmoid diverticulitis. Much less common but occasionally reported is free perforation into the peritoneal cavity occurring soon after the onset of symptoms.[1] The two cases reported here differ, however, from any we have been able to find reported in the literature. Not only was perforation not preceded by symptoms or signs of diverticulitis, but at operation no inflamed diverticula were noted, although diverticula containing inspissated feces were palpated on either side of the perforation in both instances. We believe it is important to call attention to the possibility of spontaneous perforation in the presence of diverticulosis. In operating on patients with acute abdominal conditions, the surgeon at times discovers peritonitis without obvious cause. We are convinced from our experience with these two patients that the possibility of perforation of the sigmoid colon should not be dismissed in these instances because of the lack of inflammatory signs in the sigmoid and that a most painstaking examination of the sigmoid may at times be required to locate the perforation. The presence of diverticulosis should alert the surgeon to this possibility.

REPORT OF CASES

Case 1.—A 65-year-old white man entered the Hospital of the University of Pennsylvania March 8, 1952, because of abdominal pain, which had begun suddenly three hours previously. Prior to this illness he had considered himself in excellent health and had been working as a laborer. Careful questioning elicited no admission of previous symptoms of gastrointestinal disease. The pain for which the patient came to the hospital was generalized and severe, and soon after the onset of pain he began to vomit.

On examination, immediately after admission, the patient was thought to be in shock, as evidenced by pale, cold, sweaty skin, a weak pulse, and a blood pressure of 70/40 mm. Hg. Peristalsis was not audible. The rectal temperature was 103 F. The abdomen was tender throughout, with generalized muscular rigidity and rebound pain. A rectal examination disclosed no abnormalities. The hemoglobin level was 12.5 gm. per 100 cc. (Klett-Summerson photoelectric colorimeter), and the leukocyte count was 19,000 per cubic millimeter. Urinalysis showed no abnormalities.

Whole blood was given intravenously, and within 45 minutes the patient's blood pressure had risen to 125/55 mm. Hg. A diagnosis of a massive mesenteric vascular occlusion was made, and the patient was operated on by one of us (W. T. F.), with general anesthesia administered by means of endotracheal technique, about 90 minutes after admission. The peritoneum was opened by an incision in the lower midline. Feces were noted in the right lower quadrant of the peritoneal cavity, but no perforation was found in the appendix, cecum, or ascending colon. Diverticula containing inspissated feces were palpated in a 6 in. (15.2 cm.) segment of midsigmoid colon, but no signs of inflammation were apparent, and no perforation was readily visualized. This portion of the colon was mobilized by division of the lateral peritoneal reflexion. A careful examination of the area showed a 1½ cm. perforation on the antimesenteric border hidden beneath a normal appearing fat tab. An 8 in. (20.3 cm.) segment of sigmoid colon with the perforation at its center was exteriorized through a left lower quadrant stab wound. The edges of the perforated bowel were sutured about a soft rubber tube.

After the operation the patient was treated with continuous gastric suction drainage, intravenously administered fluids, penicillin, and streptomycin. On the seventh postoperative day the exteriorized segment of sigmoid was excised by electric cautery. The patient was discharged March 23, 1952, with his wounds well healed, his colonic stoma functioning well, and his temperature normal. On April 24, he was readmitted for closure of the stoma. Roentgen examination of the colon prior to closure showed diverticulosis without evidence of diverticulitis. The patient had an uneventful recovery after stoma closure, and, at the time of discharge, May 14, 1952, he was having normal bowel movements. Since that time he has been well.

Case 2.—A 57-year-old white man entered the Hospital of the University of Pennsylvania Aug. 8, 1952, because of severe abdominal pain of three hours' duration. The pain had begun suddenly during defecation, immediately after the patient had eaten a normal breakfast. The pain radiated from the periumbilical region to both sides of the abdomen. The patient tried to take a sodium chloride solution enema soon after onset of the pain but stopped after administering one cupful because of exaggeration of the pain. The patient had considered himself to be in good health until this illness.

Physical examination after admission to the hospital revealed an acutely ill man with excruciating abdominal pain. The blood pressure was 130/80 mm. Hg, the pulse rate was 80 beats per minute, the respiratory rate was 22, and the rectal temperature was 100 F. Peristaltic sounds were not heard. The entire abdomen was rigid and tender, but the symptoms were severest in the right upper quadrant. No tenderness or masses were noted on rectal examination. The hemoglobin level was 15 gm. per 100 cc., and the leukocyte count was 14,500 per cubic millimeter. Urinalysis showed no abnormalities.

The patient was operated on by one of us (W. T. F.), with general anesthesia administered by means of an endotracheal technique, about one and a half hours after admission. Because the signs were severest in the right upper quadrant, a preoperative diagnosis of perforated duodenal ulcer was made, and the abdomen was opened by a short incision in the right subcostal region. Cloudy fluid was present in the right upper quadrant, but no perforation could be found. Palpation of the lower abdomen through the upper abdominal incision revealed free feces in the peritoneal cavity. An incision in the lower right rectus region was then made. The lower peritoneal cavity contained feces and large, undigested food particles. Several diverticula containing inspissated feces were palpated in the sigmoid colon, but no hyperemia, fibrinous exudate, or other sign of diverticulitis was noted. A careful search of the involved area of sigmoid, after mobilization by division of the lateral peritoneal reflexion, showed a 1 cm. perforation in the midsigmoid on the antimesenteric border. About 8 in. of the involved segment was brought out through a stab wound in the left lower quadrant, and the edges of the perforation were sutured about a soft rubber tube.

Postoperatively, the patient was treated with blood and other intravenously administered fluids, penicillin, streptomycin, and intestinal suction drainage with a Miller-Abbott tube. His postoperative course was good, except for the development of a wound infection in the upper part of the right rectus wound.

From the Harrison Department of Surgical Research, University of Pennsylvania School of Medicine, and the Department of Surgery, Hospital of the University of Pennsylvania.

Surg. 93: 782-785, 1931. Taylor, V. J. M.: A Case of Perforated Diverticulitis, Brit. M. J. 1: 1124-1125, 1932. Lazarus, J. A.: Perforated Sigmoiditis with Generalized Peritonitis, Am. J. Surg. 22: 284-289, 1933.

He was discharged Sept. 12, 1952, afebrile and with the colonic stoma functioning well. His stoma was closed without incident in January, 1953, and he has since been well.

COMMENT

Although diverticula were present in the sigmoid colon in these two patients, no signs of diverticulitis were noted at operation, and no symptoms indicating bowel inflammation had been present before the sudden onset of acute pain, indicating perforation. We do not know the cause of the perforation in either instance, but we believe tightly packed feces in a diverticulum may have produced obstruction and gangrene of the wall of the diverticulum. The perforation was almost certainly sudden in both instances, as indicated by the sudden onset of the symptoms and the absence of signs of a walling-off process at operation. Unless the sigmoid colon had been mobilized and carefully examined in these two instances, the perforation would not have been found. The only sign pointing to the perforation was the presence of surrounding diverticula, which were not inflamed.

SUMMARY

Two cases of spontaneous perforation of the sigmoid colon in the presence of diverticulosis are reported. Neither patient had symptoms or signs of diverticulitis. If a careful search of the sigmoid colon had not been made, we would not have identified the perforation in either instance.

CHLOROQUINE DIPHOSPHATE IN TREATMENT OF DISCOID LUPUS ERYTHEMATOSUS

Leon Goldman, M.D.
Donald P. Cole, M.D.
and
Robert H. Preston, M.D., Cincinnati

Since the initial success of the treatment of lupus erythematosus with quinacrine (Atabrine) by Prokoptchouk [1a] and Popoff and Kutinscheff [1b] and later by Page,[2] in Europe, attempts have been made to find other less toxic antimalarial agents. Numerous investigators [3] in this country also have had good results with the use of quinacrine in this disorder, but they have warned about its toxic effects, which may include production of fatal aplastic anemia.[3b]

After conferences with Dr. Leon Schmidt,[4] director of malarial research at the Institute of Medical Research, Christ Hospital, chloroquine was selected as investigative material, because it is distinctly less toxic, it may be found in the skin in appreciable amounts after oral ingestion, and it does not discolor the skin as does quinacrine. A review of the literature and our own experience revealed that the toxic effects of chloroquine diphosphate are insignificant. Toxic symptoms may include pruritus, nausea, anorexia, diarrhea, headache, difficulty in visual accommodation, and weight loss.[5] Rarely, lichenoid dermatitis may occur.[6] With Dr. Schmidt, we are now making detailed assay studies of the patterns of serum and skin distribution of chloroquine diphosphate.

Patients receiving chloroquine diphosphate for lupus erythematosus have been under observation for six months. The average dose has been 0.25 gm. twice daily for one or two weeks followed by 0.25 gm. daily for four to six weeks. In some patients the initial dose was 0.25 gm. three times daily for one or two weeks. These preliminary studies indicate that chloroquine diphosphate is as effective as quinacrine in the treatment of discoid lupus erythematosus (see the table). In some patients the initial response appeared to be slower than is usually the case with quinacrine. New lesions developed in three patients while they were receiving treatment, although the previous lesions continued to improve. It is important to note that two patients who had severe nausea and emesis as a result of quinacrine therapy tolerated chloroquine without difficulty. Only one patient in the entire series was unable to continue chloroquine therapy because of repeated nausea and emesis, although the patient's condition was greatly improved by this therapy. Another possible toxic reaction is weight loss. One patient with chronic discoid disseminated lupus erythematosus reported a weight loss of 18 lb. (8.2 kg.) during the 11 week period she received the drug, but she showed great improvement. One patient with subacute disseminated lupus erythematosus had abdominal cramps after each dose, and one with the same form of the disease had diarrhea while taking the drug. Both these patients continued treatment, with improvement in their conditions. Chewing gum has been used to partially relieve the unpleasant aftertaste of which some patients complained. Although three patients in this series had subacute disseminated lupus erythematosus, it is not recommended at present that such patients be included in routine clinical surveys.

Results of Use of Chloroquine Diphosphate in Lupus Erythematosus

Type of Lupus Erythematosus	No. of Patients	Average Duration of Therapy, Wk.	Results		
			Great Improvement	Improvement	No Change
Chronic discoid localized	12	7	7	0	5
Chronic discoid disseminated	6	11	4	2	0
Subacute disseminated	3	9	3	0	0

From the Department of Dermatology and Syphilology of the University of Cincinnati College of Medicine.

The chloroquine diphosphate used in this study was supplied by Winthrop-Stearns, Inc., New York.

The analyses for chloroquine were done by Dr. Leon H. Schmidt, Director, Institute of Medical Research, Christ Hospital, Cincinnati.

SUMMARY

Preliminary clinical trials have shown chloroquine diphosphate to be of value in the treatment of the chronic discoid phase of lupus erythematosus. This antimalarial agent is less toxic than quinacrine (Atabrine), but, with prolonged administration, the possibility of the occurrence of toxic symptoms must be considered.

ALLERGIC REACTION TO STREPTOKINASE-STREPTODORNASE SOLUTION GIVEN INTRAPLEURALLY

W. Orr Goehring, M.D.
and
John J. Grant, M.D., Pittsburgh

The use of streptokinase and streptodornase recently has gained much popularity, especially in the treatment of hemothorax in which clotted blood and fibrinous and purulent accumulations are present. Usually these enzymes are injected intrapleurally in the form of a freshly made sodium chloride solution. They cause a rapid dissolving of the blood clots and fibrinous exudates, thus facilitating removal of the material by aspiration.

Since streptokinase and streptodornase are antigenic, the possibility of the occurrence of dangerous anaphylactoid reactions, especially when the enzymes are injected intrapleurally, should be considered and watched for. Until recently, no severe reactions have been reported, except that in a case in which the outcome was fatal when the drug was injected intrathecally. Literature accompanying the commercial preparations of the product state that allergic reactions have been minimal but nevertheless should be watched for. Carr and Robbins,[1] in a series in which they used combined streptokinase and streptodornase intrapleurally for hemothorax, noted some temperature elevation in all their patients, and 6 of 10 patients complained of pleural pain; all had a feeling of malaise; however, no unusual reactions were noted. In a series of 48 cases, reported elsewhere but summarized by these authors, in which the drug was used similarly, no reactions were noted. Miller and Long [2] did not notice ill effects from the intrapleural administration of the drug in their series of cases. Recently, Baum and Oransky [3] reported an unusual reaction following intrapleural administration of combined streptokinase and streptodornase, which they believed was a pyrogenic and anaphylactoid reaction secondary to the administration of these enzymes. We wish to report a case similar to the one reported by Baum and Oransky, in which the patient's reaction in a subsequent skin test with the solution was strongly positive.

REPORT OF A CASE

A 51-year-old white man entered the hospital Dec. 3, 1952, complaining of pain in the left side of the chest, with shortness of breath, which had begun after an accident in which he had slipped and fallen, injuring his chest wall. A review of the patient's systems and history revealed nothing remarkable. Physical examination on admission revealed a well-developed and well-nourished man in no acute distress. The pulse rate and blood pressure were normal, and there was no external evidence of injury. On examination, the chest showed decreased breath sounds on the left side, with evidence of hemothorax. Initial blood studies showed 3,300,000 red blood cells per cubic millimeter, 10.8 gm. of hemoglobin per 100 cc. (Sheard and Sanford photocolorimeter), and 9,750 white blood cells per cubic millimeter with 64% polymorphonuclears and 36% small lymphocytes.

Results of other laboratory studies were essentially normal. Roentgenograms showed a fracture of the fourth rib on the left in the anterior axillary region and a hydropneumothorax on the left side, with a fluid level at the ninth rib posteriorly. Also, collapse of the left upper lung lobe and partial collapse of the left lower lobe were noted.

Initially, the patient was treated with penicillin intramuscularly and whole blood transfusions. Thoracentesis of the left chest was done about every third day, an average of 300 cc. of dark blood being removed with each aspiration. Since the later aspirations were not satisfactorily removing the blood because of its thickness, it was decided to inject streptokinase-streptodornase solution intrapleurally. On Dec. 15, 1952, after 420 cc. of blood had been aspirated, 100,000 units of streptokinase and 25,000 units of streptodornase in 20 cc. of a sterile isotonic sodium chloride solution was injected through the same needle into the left pleural cavity. A few hours later the patient began to have chills, restlessness, and profuse perspiration. He also had pain in the left side of the chest and complained of shortness of breath. About five hours after the injection, the patient's condition was critical, the blood pressure being 70/40 mm. Hg, the pulse rate 135 beats per minute and weak, the respiratory rate 25, and the temperature 103 F (axillary). No rash was noted. The patient was immediately placed in an oxygen tent. He was given meperidine (Demerol) and 1,500 cc. of plasma, and the dosage of the antibiotic he had been receiving was increased. His condition remained critical, and a few hours later he was given 1,000 cc. of whole blood as well as cardiac stimulants. On the morning of Dec. 16, the patient's condition was still poor; 600 cc. of dark blood was removed easily from the left pleural cavity. Blood studies at this time showed 4,140,000 red blood cells, 12.2 gm. of hemoglobin per 100 cc., and 41,500 white blood cells, with 98% polymorphonuclears and 2% small lymphocytes. A culture of the thoracic fluid at this time was negative for bacteria. That evening, the patient felt a little better; his temperature was 98.2 F (axillary), his pulse rate 112 beats per minute, and his respiratory rate 36. On Dec. 17, an electrocardiogram showed auricular paroxysmal tachycardia, and roentenograms showed a considerable increase in the amount of fluid in the left side of the chest, the upper limit being the fifth interspace posteriorly. The mediastinum and heart were displaced to the right.

After this episode, the patient began to improve. Pleuracenteses were done every two to three days, the fluid aspirated bing less viscous and a little brighter red in color. Much larger quantities were aspirated. The blood cell counts returned to normal. Subsequent roentgenograms showed a decrease in the amount of pleural effusion but also that the left lung had failed to expand fully. The patient was discharged Jan. 3, 1953, in an improved condition.

During examination of the patient about five weeks after the streptokinase-streptodornase injection had been given, a skin test was done. A wheal appeared on the right forearm after injection of the same solution that had been injected intrapleurally. Shortly afterward, severe edema and redness of the entire flexor surface of the forearm, with axillary adenitis, developed. This subsided subsequently with local therapy. The patient will soon undergo a decortication procedure on the left lung.

From the Department of Surgery, Columbia Hospital.

COMMENT

As stated, the occurrence of reactions after intrapleural use of streptokinase-streptodornase solution has not been common; however, physicians must be on the alert for such a possibility. Since in our patient no skin test was done prior to instillation of the solution, it is not possible to evaluate the significance of the severe reaction to a skin test done five weeks after intrapleural administration of the drug. Despite the increased pleural effusion, as seen in roentgenograms, this case appears to be one of anaphylactoid reaction due to streptokinase and streptodornase rather than one of shock due to hemorrhage and is reported as such.

SEVERE IMMEDIATE CONSTITUTIONAL REACTION TO PENICILLIN

Arthur R. Sohval, M.D., New York

Although unfavorable reactions to penicillin therapy are well known, the occurrence and frequency of serious, life-threatening, immediate constitutional reactions are not generally recognized. The few published reports describe two principal types of prompt systemic reaction. Fatal and near-fatal penicillin anaphylaxis has recently been reviewed by Siegal, Steinhardt, and Gerber.[1] An anaphylactic-like shock state, occasionally fatal, was discussed in a recent issue of THE JOURNAL by Mayer and others,[2] and similar cases have been recorded.[3] An entirely different type of reaction, characterized by sudden weakness and angor animi and with no recognizable evidence of hypersensitivity or circulatory or respiratory disturbance, has been described by Batchelor, Horne, and Rogerson.[4] The fact that Mayer's group observed six cases within a relatively short period of time and Batchelor's group encountered eight cases over an interval of seven months (an incidence of three cases per thousand injections) suggests that severe immediate reactions occur more often than indicated by the relatively few published cases.

This is the report of an alarming reaction that occurred in a patient immediately after intramuscular injection of an aqueous suspension of procaine penicillin. The reaction pattern did not conform to either of the two previously described major types of immediate reaction, although some features of each were manifested.

REPORT OF A CASE

The patient was a 56-year-old physician who had no personal or family history of allergic manifestations. He had received approximately 12 intramuscular injections of procaine penicillin in aqueous suspension for three separate suppurative infections during the previous two years. A questionable skin reaction followed the first injection two years ago. The reaction consisted of a fine desquamation of the palms three to four weeks after the injection. Procaine hydrochloride (Novocaine) has been tolerated without ill effects on numerous occasions. Early in the morning of Feb. 5, 1953, the patient noted malaise and had a slight cough. That afternoon he experienced several shaking chills, and his temperature rapidly rose to 105.8 F. Examination disclosed no etiological findings, and he was given an antipyretic mixture containing acetylsalicylic acid, acetophenetidin, and codeine sulfate. The next morning the patient's temperature was 104 F, and the sputum was blood-tinged. When he was examined at 3 p. m., the temperature was 104.2 F, the pulse 120 per minute, and the respiratory rate 22 per minute. The chest was clear. The leukocyte count was 23,600 per cubic millimeter, of which 39% were nonsegmented, and 53% were segmented polymorphonuclear neutrophils. Because of the sanguinous sputum and the sustained hyperpyrexia, a streptococcic pneumonia was suspected, and antibiotic therapy was instituted. An aqueous suspension of crystalline procaine penicillin G (Crysticillin), containing 600,000 units in 2 ml., was administered intramuscularly in the left buttock with the patient in a prone position. Concurrently, 500 mg. of erythromycin, an antibiotic derived from Streptomyces erythreus, was administered orally, and was to be repeated at six hour intervals. Six hours later the temperature was 103 F, and the pulse and respiratory rates were 118 and 20 per minute respectively. For the first time fine crepitant rales were heard over both lower lung fields posteriorly. Another injection of procaine penicillin G suspension, (Flo-Cillin) 1 million units in 1.7 ml., was given in the right buttock. On the morning of the third day there was marked subjective improvement, and the temperature was 101 F, dropping to 100.2 F in the afternoon. The pulse and respiratory rates were 80 and 20 per minute respectively. Another intramuscular injection of 1 million units of procaine penicillin G suspension in 1.7 ml. was administered in the left buttock. This was given 18 hours after the second injection, and the same technique was used in all three instances, with the usual precaution of withdrawing the syringe plunger prior to injection. There was no reason to suspect penetration of a blood vessel, and the site of injection was not massaged.

Immediately on withdrawal of the needle after the third injection, the patient complained of vertigo, which became more intense as he turned over to the supine position. Simultaneously, he complained of a peculiar metallic taste in his mouth and a sense of nasal obstruction. He also had a feeling of thoracic constriction and warmth as well as severe palpitations. For a few seconds the patient was unable to move his right upper and lower extremities. His speech was slurred, and his tongue felt "thick" for approximately 10 minutes. During this time there was an ashen gray pallor of the face, and the pulse was full and bounding, with a rate of 150 per minute. There was no sweating, faintness, or evidence of bronchial or laryngeal obstruction. The patient displayed intense anxiety and fear of impending death, accompanied by a staring expression and hyperventilation. Overbreathing promptly stopped when it was called to the patient's attention. Since there was no circulatory collapse or respiratory embarrassment, no medication was administered. Recovery from the alarming phase of the reaction (vertigo, hemiparesis, slurred speech, palpitations, thoracic compression, and angor animi) was complete in 15 minutes. The temperature fell to normal levels that evening, and there was rapid clearing of the pulmonary findings under continued administration of erythromycin. A feeling of fatigue persisted for a day. The patient had fully recovered on the eighth day of the illness. Skin sensitivity tests, passive transfer studies, and precipitin reaction tests were not performed.

COMMENT

The reaction pattern in this patient is difficult to classify. It lacked the manifestations of shock, dyspnea, sweating, and disturbances of consciousness that characterize anaphylactic or nitritoid reactions. On the other hand, vertigo, transitory neurological phenomena, an odd taste in the mouth, sense of thoracic compression, and

angor animi present in this case have been described in anaphylactic-like reactions to procaine penicillin. Dizziness, weakness, "fluttering in the chest," peculiar taste, and angor animi were also encountered by Batchelor, Horne, and Rogerson [4] in a series of reactions that they believed were entirely nonallergic. So firm was their conviction in this respect that five of their eight patients were subsequently re-treated with the same drug without untoward results.

CONCLUSIONS

In view of the gravity of immediate constitutional reactions to penicillin in its various forms, it is hardly necessary to stress careful selection of patients. Therapeutic indications should be rigid. Screening to eliminate persons with previous histories of untoward penicillin reactions is necessary but is not foolproof. Meticulous attention to injection technique, in order to avoid entry of penicillin into the blood stream, is also essential but does not assure that unrecognized penetration of a vein will not occur. Finally, emergency medication consisting of an injectable vasoconstrictor and an antihistaminic should be immediately available.

It is hoped that more diligent reporting and compilation of casuistic data may lead to an improved understanding of the various pathogenetic mechanisms and to reduction or elimination of serious reactions to penicillin.

ADDENDUM

Since this report was prepared, the problem of immediate anaphylactic reactions to penicillin has received further attention.[5] Severe constitutional reactions were recorded in seven patients with a fatal outcome in five.

1155 Park Ave.

[5] Feinberg, S. M.; Feinberg, A. R., and Moran, C. F.: Penicillin Anaphylaxis: Nonfatal and Fatal Reactions, J. A. M. A. 152: 114 (May 9) 1953.

The Nervous Child.—The discussion deals with an amorphous group whose symptoms are not definite enough to be dignified with such titles as anxiety neurosis et cetera. The mother will say that he is very highly strung or that his nerves are bad; that he is too sensitive; that he is prone to tears. . . . The teacher may complain that the child is restless, cannot concentrate or fix his attention. Various behaviour disorders may be added to the picture; habit disorders such as stammering, bed-wetting, nail-biting, skin-picking and masturbation appear from time to time. . . . These children are just too soft and give excessive emotional response to ordinary stimuli. They need to be toughened and to be assisted to acquire reasonable emotional control. The phrase used as the title, "The Nervous Child" has a bad influence. When a parent is told that his child has bad nerves, it conveys to him that there is a disease process in very vital tissues. And disease calls for protection. With the added protection the subject becomes still more sensitive. Thus a vicious circle is established. . . . Yet, if one can convey to the parent that his child is emotionally ill while the nervous system is organically quite sound, it produces an entirely different orientation. Instead of looking for direct intervention by the doctor, he will begin to seek for factors in the environment. . . . One must especially guard against a sudden change from coddling to a Spartan regime. One may point out that a limb which has been protected by a splint for any length of time will be very soft and sensitive at first. It will need carefully graded exercises until it gradually regains its strength and is able to function like the normal one. A hothouse plant, if suddenly exposed to the elements, will succumb; but if protection is withdrawn little by little the adaptation process will go on until the hothouse plant becomes as tough as the plant that grew outside from the beginning.—H. M. North, M.D., The Nervous Child, *Medical Journal of Australia,* May 2, 1953.

A SYRINGE SHIELD USED IN INJECTING RADIOACTIVE GOLD

Paul Getzoff, M.D.
John Hidalgo, M.S.
and
Joe Meyer, Ph.D., New Orleans

Since the introduction by Flocks and others [1] of the concept and technique of employing radioactive gold (AU^{196}) in the treatment of prostatic carcinoma, we have been interested in this fresh approach and the promising results obtained. We have found Flocks' operative method completely satisfactory. The technique for concentrating a solution of radioactive gold in the prostate gland consists of the direct injection of the material into the organ suprapubically, retropubically, and through a spinal needle inserted perineally. Obviously, certain problems are involved with any method that includes use of radioactive isotopes.

The broad principles involved in this operation may be briefly summarized as follows: 1. The radioactive gold must be injected in such a manner as to assure maximum diffusion of the solution throughout the prostate gland. 2. Retrograde leakage through the tract produced by the needle should be minimal. 3. Depth of the injection must be completely controlled so that the rectal wall is not penetrated. 4. The surgeon, his assistants, and other operating room personnel who handle the "hot" syringe must be guaranteed reasonable safety.

We have designed and used successfully a simple syringe shield constructed to fulfill the requirements described. When the radioactive gold solution is injected with various syringes, the stony indurated character of the malignant prostatic tissue is manifested by the difficulty encountered in forcing the solution into the glandular substance. Our apparatus has considerable mechanical advantage. The surgeon is able to inject the solution with almost "finger tip" ease and with both mechanical preciseness and a minimal loss of the solution by leakage back into the bladder through the sites of injection. The screwing motion of injection obviates the possibility of "binding" between the plunger and barrel of the syringe and minimizes the danger of the syringe breaking during the injection. The latter has been a frequent occurrence with ordinary syringes. Safety factors, which are of inestimable importance in the handling of radioactive material, are preserved. The syringe is handled with complete ease by the physicist and operating personnel. This instrument is easily made by a skilled machinist. It is economical, sturdy, easy to clean, and can be conveniently assembled and disassembled in a few seconds.

An additional feature is the guard placed on the needle. Spinal needles (19 gage) are fitted with easily adjustable guards that resemble the type used on ornamental tie pins. The desired depth of injection is estimated, and the guard is adjusted accordingly by the

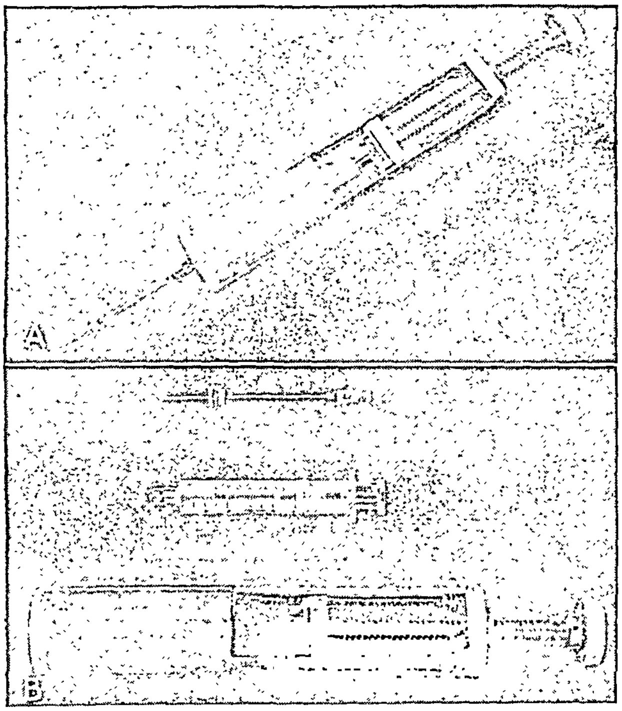
From the departments of urology and biophysics, Touro Infirmary, the Department of Physics, Tulane University, and the Radioisotope Unit, Veterans Administration Hospital, New Orleans.

[1] Flocks, R. H.; Kerr, H. D.; Elkins, H. B., and Culp, D.: Treatment of Carcinoma of the Prostate by Interstitial Radiation with Radio-Active Gold (Au198): Preliminary Report, J. Urol. 68: 510-522, 1952.

physicist in charge of filling the syringes. Several needles are kept available with the guards adjusted to suit variable conditions in the same patient. The use of these needle guards has made possible greater accuracy and safety in injections into nodular glands where the penetration distance differs at various sites.



A, shield enclosing syringe for injection of radioactive gold solution; *B*, shield, syringe, and needle with adjustable guard.

The outside diameter of the shield is 1⅞ in. A 10 cc. Luer-Lok syringe is surrounded by a shield of lead 7/16 in. thick and encased in a brass tube ⅛ in thick. The drive screw is double threaded, with a ¼ in. pitch providing a mechanical advantage of 5.5×. The syringe plunger is 0.25 square in. in cross section. This adds a factor of 4× for pressure units. Thus, a force of 1 lb. exerted on the perimeter of the screw will yield 5.5 (mechanical advantage of drive screw) × 4 (pressure units factor) × 1 (lb. of exerted pressure) = 220 lb. per square inch. The knob also adds some mechanical advantage. It has a diameter of 1½ in. and a radius of 7/32 (0.218) in. A ratio of the imparted force (F) to the resultant force (R) is a measure of the effective radii.

$$\frac{F}{0.625} = \frac{R}{0.218}$$

$$\frac{F}{R} = \frac{0.625}{0.218} = 2.87$$

Mechanical advantage obtained with 1 lb. of pressure applied to the perimeter of the screw is as follows:

Mechanical advantage 22.0 × 2.87 = 63.1 ×

The markings on the guide bar are calibrated into 10 divisions indicating 1 cc. each. This enables the physician to measure with reasonable accuracy (i. e., by observing the pointer) the millicuries in the solution being injected.

SUMMARY

A new and simple type of syringe shield is described for use in the injection of radioactive gold (Au^{198}) in carcinoma of the prostate gland as described by Flocks and others.[1] The device is economical and is devoid of complicated delicate adjustments.

This apparatus makes possible effective, safe, accurate, and relatively easy injection by virtue of its high mechanical advantage (63.1 ×). Its value is further enhanced by an adjustable guard placed on the needle, which prevents the insertion of the needle beyond a predetermined point.

SALMONELLA MONTEVIDEO INFECTION FOLLOWING USE OF POWDERED EGG YOLK

Capt. Samuel C. Southard (MC), Army of U. S.
Major Walter B. Watson
and
Capt. Arnold J. Capute, (MC), U. S. Army

The following case of Salmonella montevideo infection is reported because of the unusual probable source of infection, dry powdered egg yolk. In giving treatment for or attempting to prevent recurrences of such infections, physicians should consider this possible source. A letter was sent to the packing company to determine whether this strain of S. montevideo had been isolated from their product, dry powdered egg yolk. They replied immediately that they had been informed by the Federal Food and Drug Administration that S. montevideo had been recovered from the dry egg yolk tested in the Food and Drug Administration laboratories but that this finding had not yet been confirmed by their own laboratories.

REPORT OF A CASE

A 3-year-old white girl was admitted Nov. 13, 1952, to the pediatric service of the U. S. Army Hospital, Fort Hamilton, Brooklyn, N. Y., with the chief complaint of diarrhea. The patient had been under the care of this hospital's pediatric service for the previous year and had been known to have incomplete cystic fibrosis of the pancreas. She had been doing well and had been gaining weight by following a celiac type of diet, until four days prior to admission, when she vomited once. She had no other symptoms until diarrhea began two days prior to admission. This consisted of loose, dark brown to black, watery stools, with a small amount of thick mucus. At this point, the patient was seen by another physician, who prescribed dietary restrictions and administration of a kaolin mixture and 300,000 units of procaine penicillin intramuscularly. The white blood cell count at that time was 10,200 per cubic millimeter, with 84% neutrophils and 16% lymphocytes. The following day, diarrhea became more profuse, and the father, a physician, noted what appeared to be streaks of bright red blood. Because of the patient's history of cystic fibrosis, she was admitted to the hospital.

Physical examination on admission revealed a thin, poorly nourished child weighing 25 lb. (11.3 kg.). The throat, fauces, and tonsils were injected. The temperature was 101.4 F. The child was put to bed, was placed on an appropriate constipating diet, and was given procaine penicillin, 300,000 units intramuscularly every 12 hours. The diarrhea subsided in 24 hours. The temperature returned to normal in 48 hours, remained normal for 48 hours, and then returned to 101 F, with recurrence of the pharyngitis. This responded without difficulty to administration of additional penicillin and the usual symptomatic treatment. Results of urinalysis were normal. The white blood cell count showed a slight increase of the neutrophils but was otherwise within normal limits. A throat culture showed a hemolytic strain of type A beta hemolytic Streptococcus and a hemolytic strain of Staphylococcus aureus. Stool examination showed the presence of gross blood, and culture showed the presence of a strain of Salmonella organisms. This culture was sent to the First Army

Dr. Southard has been released from the Army and is now practicing in Ventnor City, N. J.

Medical Laboratory, where the strain was identified as S. montevideo. The child was then given a mixture of sulfadiazine and sulfamerazine while awaiting the results of sensitivity tests of the S. montevideo isolated.

Family history revealed that on Nov. 6, 1952, the girl's younger brother, aged 11 months, had had a short episode of mild diarrhea, which was treated successfully with dietary restriction and use of a kaolin mixture. On Nov. 9, the patient's mother also had a short episode of mild diarrhea, which subsided after two days without therapy. Concomitantly with the hospitalization of the 3-year-old girl, a survey of the family revealed that the patient's 11-month-old brother and her father also harbored the same strain of bacteria. The infant was admitted to the hospital to receive therapy in an attempt to abolish the carrier state. It is interesting to note that this family first used powdered dried egg yolk for the infant on about Nov. 1, 1952, and six days later diarrhea developed in him.

Sensitivity tests (broth dilution method) showed that this strain of S. montevideo was not inhibited by bacitracin, penicillin, or the sulfonamide mixture. Slight inhibitions were produced by concentrations of 10 μg per cubic centimeter of aureomycin, 30 μg per cubic centimeter of oxytetracycline (Terramycin), and 10 μg per cubic centimeter of chloramphenicol. Inhibition was produced by a concentration of 10 μg per cubic centimeter of dihydrostreptomycin. Cultures were again made, and the organisms were found to persist despite sulfonamide therapy, as was expected from the sensitivity tests.

Both children were then given 1 gm. of streptomycin orally per day in two equal doses every 12 hours. This was continued arbitrarily for five days. After a waiting period of three days, cultures were again made. Three daily cultures were negative for Salmonella. The father also took streptomycin orally under the direction of his physician. This family will be followed for six months to make certain that the carrier state has been abolished.

SUMMARY

A case of Salmonella montevideo infection in a 3-year-old girl following use of powdered egg yolk is reported. The child's father and infant brother were also found to be harboring the organism, which was shown to be sensitive to streptomycin. All three were treated and will be followed until the carrier state has been eliminated.

7217 Atlantic Ave., Ventnor City, N. J. (Dr. Southard).

Today's Family Doctor.—Pendulums inevitably swing too far and then come back. Today the swing is back to a proper regard for the family physician. We might say a proper regard for the new family physician. Who is this new family physician? He is a man or woman who has completed six years in university study and has spent an average of two years in hospital training, following graduation. He is well versed in modern methods of diagnosis and treatment. He knows his limitations in treating cases which may require specialist care. He takes time off each week for study in his neighborhood hospital and each year takes a refresher course in some aspect of his work. He is fully trained in the aspect of medicine which reveals nearly every disease—the ability to evaluate the patient's story about his illness, and the ability to do a thorough physical examination. Relatively few cases require diagnostic aids other than those in daily use in the family doctor's office; and relatively few cases require treatment other than that which the family doctor is able to give.—G. I. Sawyer, M.D., Every Family Needs a Doctor, *Health*, May-June, 1953.

COUNCIL ON PHYSICAL MEDICINE AND REHABILITATION

APPARATUS ACCEPTED

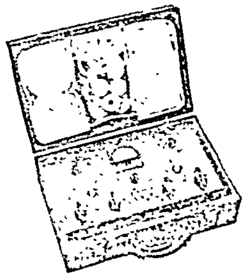
The following additional products have been accepted as conforming to the rules of the Council on Physical Medicine and Rehabilitation of the American Medical Association for inclusion in Apparatus Accepted. A copy of the rules on which the Council bases its action will be sent on application.

Ralph E. De Forest, M.D., *Secretary*.

Multitone Muscle Stimulator, Model 3

Bilton Laboratories, Inc., 100 S. Broad St., Philadelphia 10.

The Multitone Muscle Stimulator, Model 3, is an apparatus for generating electric currents to stimulate innervated voluntary muscles as an aid in rehabilitation, to retard muscle atrophy, and to prevent adhesions and joint atrophy in patients who cannot exercise voluntarily. The apparatus weighs 11.3 kg. (25 lb.) and is portable. It requires a source of 60-cycle alternating current at 110 volts and draws 22 watts.



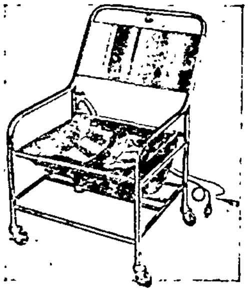
Multitone Muscle Stimulator, Model 3

It is equipped with eight circular electrodes so that more than one muscle can be exercised at a time. A selector switch set at "Push-Pull" energizes the right and left circuits alternately and thus makes it possible to elicit reciprocating contractions of antagonistic muscle pairs. Other controls permit adjustment of intensities and frequencies. The apparatus is accepted for use under medical supervision in stimulating normally innervated muscles.

Ille Mobile Sitz Bath, Model SB 100

Ille Electric Corporation, 50 Mill Road, Freeport, Long Island, N. Y.

The Ille Mobile Sitz Bath is a metal chair with the seat modified for application of heated water to the perineal region. It is intended for use in treatment or postoperative care in gynecologic, obstetric, and rectal cases. A heater maintains the temperature of the water during the interval between filling of the bath and immersion of the part to be treated. The heating unit operates on either direct or alternating current at 115 volts and draws 325 watts.



Ille Mobile Sitz Bath, Model SB 100

The chair frame is made of aluminum tubing; the water pan is of stainless steel. The unpacked article weighs 13.6 kg. (30 lb.) and measures 89 by 74 by 61 cm. (35 by 29 by 24 in.). Packed for shipment it measures 102 by 76 by 76 cm. (40 by 30 by 30 in.) and weighs 38.6 kg. (85 lb.). The apparatus has the approval of Underwriters' Laboratories, Inc.

TRANSFUSION OF PLATELETS

Uncontrolled hemorrhage due to thrombocytopenia may occur not only in essential thrombocytopenia but also in secondary thrombocytopenia such as may follow treatment of leukemia with myelotoxic agents or exposure to ionizing radiation. Such a hemorrhage responds poorly to transfusion of blood obtained from blood banks, presumably because the platelets are quite unstable under the conditions of collection and storage. Consequently, in recent years attention has been directed toward development of improved methods for the collection, storage, and administration of platelets. The current status of this work has been reviewed by Stefanini and Dameshek[1] together with a summary of their clinical experiences over a three year period.

Stefanini and Dameshek point out that in ordinary blood bank procedures agglutination and destruction of platelets is favored by their contact with such foreign surfaces as glass and metal and by the foaming that may result from the use of a vacuum. Indeed, it has been found that transfusions of blood obtained from blood banks do not elevate the platelet counts of thrombocytopenic recipients appreciably.

Several technical procedures are now available, however, that permit increased survival of platelets in vitro and in vivo. Thus a number of materials are available for coating metal surfaces or glassware with nonwettable endothelial-like surfaces[2] such as Arquad 2-C (dicocodimethyl-ammonium chloride) for coating needles, silicone lacquer, and Teflon fluid (a tetrafluoroethylene resin preparation) for coating metal surfaces, and silicone (methyl-chloro-silane) for coating glassware. Collection of blood without great loss of platelets is possible if such coated metal and glassware are used as well as tubes of nonwettable plastic or equipment made entirely of plastic. A new anticoagulant, Sequesterene disodium (disodium ethylenediamine tetra-acetate), minimizes the tendency of platelets to become sticky, to agglutinate rapidly, and to undergo morphological alterations in shed blood.[3] Other measures for more efficient separation and concentration of platelets include the use of surface acting agents such as polysorbate 80 (Tween-80) and Triton WR-1339 (an alkylaryl polyether alcohol) to reduce irreversible agglutination of platelets[4] and of ion-exchange resins such as Dowex-50 for the removal of platelets from blood. The resins trap the platelets as the blood that flows through is decalcified and made incoagulable. Platelets can then be recovered by elution.[5]

The clinical work described by Stefanini and Dameshek is based on a total of 216 platelet transfusions in 83 patients. Of these patients, 45 had idiopathic thrombocytopenia purpura, 33 had "amegakaryocytic" secondary thrombocytopenic purpura, and 5 had "hypersplenic" thrombocytopenic purpura. Platelet transfusions were given by various methods, including the transfusion of polycythemic blood or plasma directly with the use of multiple silicone-coated syringes, the transfusion of blood or plasma from polycythemic donors collected in and administered by plastic sets or silicone-coated glass bottles and plastic tubing, and the administration of concentrates of platelets isolated by multiple low speed centrifugation of whole blood collected by gravity in silicone-coated glassware with Sequestrene disodium used as the anticoagulant.

In comparing these methods it was found that when comparable numbers of platelets were transfused into patients with secondary thrombocytopenia, the platelets survived longest (four to five days) when platelet-rich polycythemic blood was transfused directly. The second longest survival period was with polycythemic blood collected in silicone-coated bottles or plastic bags. Platelets survived for much shorter times when they were separated and resuspended in their own plasma, while almost no platelets survived when they were resuspended in saline solution before being administered. These results agree well with results of in vitro studies, which demonstrated, among other things, that platelets that were resuspended in plasma still had the ability to normalize the clot retraction of platelet-poor plasma after they had been stored for 10 days at 51 C, while platelets that were resuspended in saline solution lost this ability after 10 to 24 hours.

Stefanini and his co-workers have found that administration of platelets to patients with either a quantitative or a qualitative platelet deficiency results in more complete retraction of the clot, reduction of the bleeding time, more complete utilization of prothombin during clotting, and improvement of the capillary fragility and of the bleeding manifestations. While better results were obtained with platelet-rich blood or plasma than with isolated platelets, in all cases the effects were manifested for some time after the injected platelets had disappeared from the circulation. This finding suggests that the hemostatic effect of platelets is due, in part at least, to relatively stable constituents of platelets liberated when these bodies integrate.

5. Freeman, G.: Method for Obtaining Large Yields of Human Platelets as By-Product of Blood-Collection, Science **114**: 527-528, 1951.

The value of platelet transfusions is limited by the fact that the survival of platelets in vivo is considerably reduced by the pathological state of the recipient. Stefanini and his associates feel that this response is in some cases nonspecific, but in others a platelet-destructive mechanism appears to be the important factor. Survival of transfused platelets is greatly reduced in severe transfusion reactions and in severe, uncontrolled hemorrhage. Splenomegaly, irrespective of its etiology, may cause fast disappearance of platelets. Platelet-destructive mechanisms are present in idiopathic thrombocytopenic purpura and in thrombocytopenia due to drug sensitivity when the causative drug is still in the circulation. Furthermore, repeated transfusions of platelets or platelet products may give rise to decreased platelet survival owing to the appearance of platelet agglutinins. It is possible that this is due to the administration of mismatched thrombocytes, since preliminary evidence suggests there may be platelet groups in human beings.

The results thus far obtained with the use of platelet transfusions would seem to justify a continued search for better methods of platelet isolation and for the identification of the factor or factors in platelets responsible for their hemostatic effects. Such studies not only offer a promising therapeutic approach but may well throw further light on the pathogenetic mechanisms in certain thrombocytopenic states.

THE BIOSYNTHESIS OF CHOLESTEROL

The availability of isotopes for "labeling" suspected precursors of biologically important substances made possible the fundamental discovery that the simple, abundant 2-carbon compound, acetate, is used in the biosynthesis of cholesterol.[1] Atoms of radioactive carbon (C^{14}) derived from acetate administered to experimental animals were found to appear in the cholesterol subsequently isolated from the tissues. Recent work has further demonstrated that the synthesis of cholesterol from acetate proceeds by way of the cyclization of the hydrocarbon squalene.[2] The site and the regulation of the biosynthesis of cholesterol are also problems of great medical interest and fundamental importance. The liver appears to be the primary locus of cholesterol synthesis in the adult,[3] whereas other tissues, including the kidney, testes, adrenal cortex, ovaries, and small intestine, are active in the fetus.[4] The skin also contributes somewhat to cholesterol synthesis in the adult.

A number of factors have been shown to affect the rate of synthesis of cholesterol, particularly in the liver. One of the most interesting of these is cholesterol itself.[5] With liver slices to which C^{14}-acetate was added, the rate of hepatic synthesis of cholesterol was carefully followed in control, untreated dogs and in dogs previously fed relatively large amounts of cholesterol. A very low rate of synthesis was found in the cholesterol-fed group. This observation is perhaps not an unexpected one. The presence or accumulation of the end-product of most reactions, particularly enzymatic, inhibits any further reaction. As another example, the continued administration of a hormone is typically attended by a decreased production of the same hormone by the endocrine gland involved, even to the point of atrophy of the secretory tissue. In the case of cholesterol, this is perhaps a fortunate coincidence in the protection of the organism against an oversupply of cholesterol and in maintaining homeostasis with respect to this sterol. Furthermore, these observations may add to the now considerable amount of evidence indicating that an increased cholesterol intake is not an etiological factor in supposed aberrations of cholesterol metabolism, such as atherosclerosis.

Two other important factors affecting the biosynthesis of cholesterol are being studied currently. One of these is pantothenic acid.[6] In studies on rats, a group of California investigators observed that there is a decreased synthesis of cholesterol by the liver in pantothenic acid deficiency. This is a rather reasonable finding, since pantothenic acid is a constituent of coenzyme A, which is required for the metabolism of acetate, which, in turn, serves as a precursor of cholesterol as mentioned above.

A second vitamin currently indicated to be involved in the regulation of cholesterol formation, at least in the adrenal, is ascorbic acid.[7] The preliminary results show that the adrenal glands of the severely scorbutic guinea pig incorporate six times as much C^{14}-labeled acetate into cholesterol as do those of normal control animals under otherwise identical conditions.

The recent studies described above indicate that the biosynthesis of cholesterol is a delicately controlled mechanism that is not only adapted, on the one hand, to insure an adequate supply of this extremely important essential metabolite in the body but also regulated, on the other hand, to prevent an oversynthesis in potentially dangerous amounts.

PATHOGENESIS OF ESSENTIAL HYPERTENSION

The pathogenesis of essential hypertension, which accounts for 95% of the cases of hypertension seen clinically, is still unknown in spite of extensive clinical and laboratory studies during the past 20 years. However, these studies have indicated neurogenic, endocrine (anterior pituitary–adrenal cortex), and renal changes in pathophysiology that may have pathogenetic significance. Thus some patients with essential hypertension show evidence of increased vasomotor tone, others show mild disturbances in water and sodium chloride metabolisms, and some show increased plasma concentrations

of vasoexcitatory material (VEM) and vasodepressor material (VDM), produced by the kidney and liver, respectively. Whether these changes connote several pathogenetically distinct types of hypertension or whether essential hypertension is a single clinical entity with varying degrees of alteration in different body functions remains to be determined.

Since the pathogenesis of essential hypertension is unknown, treatment is based on pathophysiology and empiricism. Moreover, information about the long-term effects of presently recognized methods of treatment (psychotherapy, sedatives, low salt diet, autonomic drugs, and sympathectomy) on the basic hypertensive vascular disease process is incomplete and largely limited to sympathectomy. That these types of therapy afford symptomatic relief in some patients has been amply demonstrated; that they prolong life in some is probable; but that they are capable of delaying the progress of the basic cardiovascular disease in most patients can only be conjectured at present. Since all these methods of treatment have an antihypertensive effect in certain patients and hypertension is known to accelerate the onset and accentuate the progress of atherosclerosis and arteriolosclerosis, long-term antihypertensive therapy should at least decrease the incidence and severity of arteriosclerosis in essential hypertension.

The reproduction of a disease in experimental animals has almost invariably led to better understanding of the disease and hence to better therapy. Accordingly, many attempts have been made to reproduce essential hypertension experimentally. Thus far, these efforts have resulted in important progress rather than complete success. Section of the carotid sinus and aortic depressor nerves is very efficient in producing hypertension due to increased vasomotor tone; however, this hypertension is characterized by tachycardia and absent buffer nerve function and, therefore, differs importantly from essential hypertension. Large doses of crude anterior pituitary extract or of its somatotropic hormone and large amounts of desoxycorticosterone acetate and sodium chloride produce hypertension in rats but not in dogs. This hypertension, however, resembles that of pituitary basophilism and adrenal cortical tumors, rather than essential hypertension. Partial constriction of the renal arteries in all species of animals studied produces hypertension [1] that in all important respects thus far studied resembles essential hypertension. Obviously it cannot be concluded that these similarities indicate even a partial common pathogenesis for the two conditions, but the similarities encourage study of the pathogenesis and treatment of experimental renal hypertension in the hope that the enigma of essential hypertension will be brought nearer to solution.

Although 20 years have passed since Goldblatt first produced experimental renal hypertension, its pathogenesis is still unsettled. The three principal hypotheses are alteration in the renin-angiotonin (hypertensin) mechanism, decreased secretion of a renal blood pressure regulating hormone, and increased formation of pressor amines by the kidney. Recently a research group at the University of Illinois College of Medicine offered good evidence that renin or a closely related renal protein is pathogenetic in experimental renal hypertension in dogs.[2] Experiments extending over more than a decade demonstrated that repeated injections of hog renin into dogs produced an antibody (antirenin) that neutralized the pressor effect of hog renin and also dog renin. Experimentally induced renal hypertension in dogs was successfully treated with hog renin and also prevented by prophylaxis with hog renin. The therapeutic and prophylactic effects were well correlated with the antirenin titer. Control tissue extracts were without antihypertensive effect. The same research group subsequently found that the passive transfer of high titer antiserum to dogs with chronic renal hypertension produced a significant antihypertensive effect that was also well correlated with the antirenin titer.[3] Even more important, perhaps, is the finding that similar renin-antirenin treatment of spontaneous hypertension in the dog (which may be the counterpart of essential hypertension in man) produced excellent antihypertensive effects.[4]

Unfortunately, antirenin to hog renin does not neutralize monkey or human renins; hence, semipurified hog renin was without antihypertensive effect in experimental renal hypertension in the monkey, even in the presence of good antirenin titers.[5] Negative results were also obtained with hog renin in essential hypertension, as was to be expected even if the pathogenesis of essential hypertension should ultimately prove to be primarily on a renal renin basis.[6] However, the finding that a passively produced antirenin titer is similarly effective in its antihypertensive action to a titer actively produced in chronic renal hypertensive dogs suggests a heretofore unavailable method for determining what proportion, if any, of patients with essential hypertension have hypertension on a renal renin basis. The University of Illinois group has shown that antirenin to human renin produced in the rabbit, dog, and goat neutralizes human renin. After preliminary studies in the monkey, they propose to study the effect of the passive transfer of purified antirenin to human renin in essential hypertension. Significant antihypertensive effects would suggest a pathogenetic role for the kidney and the renin mechanism. Should essential hypertension in an appreciable percentage of patients prove to be primarily on a renal renin basis, research groups that are not now interested in the problem might well be stimulated to alter the antigenicity of hog renin or other animal renins to overcome the species difference that presently precludes the possible successful use of these renins in the treatment of hypertension in human patients.

MEDICAL NEWS

CALIFORNIA

Dr. Guedel Honored.—At the Third Biennial Western Conference of Anesthesiologists, Dr. Ralph T. Knight, Minneapolis, president, American Society of Anesthesiologists, acting on behalf of the Cuban Society of Anesthesiology, presented to Dr. Arthur E. Guedel, emeritus associate clinical professor of surgery (anesthesiology) at the University of Southern California School of Medicine, Los Angeles, a scroll testifying his election to honorary membership in the Cuban society. Dr. Georgina A. Funtanellas, graduate of the University of Havana Faculty of Medicine and Pharmacy, and now head of the department of anesthesiology at the San Francisco Hospital, represented the Cuban society.

Course on Radioisotopes.—The University of California Extension offers a course in "Fundamental Principles of Radioactivity Including Clinical Use of Radioisotopes," directed particularly toward the clinical and experimental use of radioisotopes and designed to meet the requirements of the Atomic Energy Commission in respect to distribution of radioisotopes. On satisfactory completion of the course, students will be able to obtain radioisotopes directly from the Atomic Energy Commission. The 40 week course involves laboratory and lecture sessions on Wednesdays from 7 to 10 p. m., beginning Sept. 16, and clinical sessions on Wednesdays from 9 to 12 a. m. and 2 to 5 p. m., May 12 to June 30, 1954 (10 all-day sessions). Primary emphasis will be placed on laboratory work including experiments with radioisotopes as well as radioactivity detecting and counting techniques. Fee for the course is $700. The course is limited to 12 registrants, who must be graduates of approved medical schools. Application or requests for information should be made to Dr. Thomas H. Sternberg, Head of Postgraduate Instruction, Medical Extension, University of California, Los Angeles 24. Study sessions will be held at the university's School of Medicine, 10975 Wilshire Blvd., Los Angeles 24, with clinical sessions at Wadsworth General Hospital, Veterans Administration Center, Los Angeles, and Harbor General Hospital in Torrance.

GEORGIA

Narcotic Violation.—Dr. Marvin A. Acree, Calhoun, pleaded guilty in the U. S. District Court at Rome, June 3, to a violation of the federal narcotic law and on the same date was sentenced to three years' probation and was fined $500.

Society News.—The Georgia Urological Society has elected the following officers: Dr. James L. Pittman, Atlanta, president; Dr. J. Robert Rinker, Augusta, president-elect; and Dr. J. Zeb McDaniel, Albany, secretary-treasurer.——The Georgia Society of Ophthalmology and Otolaryngology has elected Dr. W. Eugene Matthews, Augusta, president; Dr. J. Kirk Train, Savannah, vice-president; and Dr. Alton V. Hallum, Atlanta, secretary-treasurer. The society's spring meeting in 1954 will be held March 5-6 at the General Oglethorpe Hotel, Savannah.

ILLINOIS

School for the Blind Teaches by Mail.—The Hadley Correspondence School for the Blind, Winnetka, will attempt to raise $115,000 in 1953 in order to erect a building to house its institution, which has grown from one pupil in 1921 to its present 1,100 in 48 states and 27 foreign countries. The school, founded by a blind Chicago high school teacher, Mr. William A. Hadley, offers some 70 courses, in addition to the fundamental lessons of Braille. No tuition is charged, the school being maintained solely through the support of interested persons.

Hospital News.—According to a recent report from the Bureau of Hospitals, State Department of Public Health, during the past decade the birth rate in Illinois hospitals has increased markedly, 197,750 babies having been born last year in Illinois hospitals licensed for maternity service, compared with 136,648 in 1943. About 98 of every 100 births in Illinois last year occurred in hospitals. As for the reduction in maternal mortality in hospitals, 77 mothers died last year from complications associated with childbirth, compared with 286 such deaths in 1943. The maternal mortality rate in hospitals declined from 21.4 deaths per 10,000 live births in 1943 to 4 in 1952. Infant mortality under one month of age fell from about 22 per 1,000 live births in 1943 to 17.7 last year.

Chicago

Cancer Gift.—A check for $1,000 recently presented to Dr. John A. Rogers, executive director of the Illinois Division, American Cancer Society, represented funds raised by the Philip Solomon Memorial Club.

Society News.—At the annual meeting the Chicago Gynecological Society elected the following officers: president, Dr. Henry Buxbaum; president-elect, Dr. Jacob P. Greenhill; vice-president, Dr. John R. Wolff; treasurer, Dr. Harry Boysen; secretary, Dr. Edwin J. DeCosta; pathologist, Dr. Arthur H. Klawans; and editor, Dr. Magnus P. Urnes.——The Chicago Society of Allergy has elected Dr. Abraham L. Aaronson, Chicago, president, Dr. Max Samter, Oak Park, Ill., president-elect, and Dr. Simon S. Rubin, Gary, Ind., secretary-treasurer.

Personal.—At a ceremony in the nurses' residence of Michael Reese Hospital, a plaque was awarded to Dr. Isaac A. Abt "in honor of his outstanding contributions to the science of healing sick children." Dr. Abt is one of the founders of the Sarah Morris Hospital for Children at Michael Reese.——Friends and fellow members of the Rush Medical alumni of the University of Chicago recently honored Dr. Ottilie Zelezny Baumrucker of the Women's and Children's Hospital for her 50 years in the practice of medicine. She was feted at a dinner in the Shoreland Hotel.——Dr. Meyer R. Lichtenstein has been named medical director of the City of Chicago Municipal Tuberculosis Sanitarium succeeding Dr. Otto L. Bettag, who resigned in January to become director of the Illinois Department of Public Welfare. Dr. Lichtenstein has been serving as acting medical director in addition to his regular duties as chief of the medical department.——Dr. Abraham Levinson, professor of pediatrics, Northwestern University Medical School, recently delivered the first annual Dr. B. Bernard Weinstein History of Medicine Lecture in New Orleans. The lecture was sponsored by the Tulane History of Medicine Society in honor of Dr. Weinstein, who is associate professor of clinical gynecology at Tulane University of Louisiana School of Medicine and faculty adviser to the society.——Dr. Earl H. Blair, deputy director for health services of the Chicago Civil Defense Corps, has been named as one of 65 volunteer civil defense workers in 34 states to receive the 1953 Freedoms Foundation civil defense awards for "rendering paramount service toward maintaining the American way of life."

KANSAS

Arkansas City Fluoridates Water Supply.—On June 11, Arkansas City became the 15th Kansas city now fluoridating public water supplies. Fluoridation of the municipal water supply in Arkansas City was endorsed by the Arkansas City and Cowley County dental societies. Other towns in Kansas now fluoridating the public water supply are Ottawa, Horton, Junction City, Garnett, Seneca, Fort Scott, Minneapolis, Hays, El Dorado, Coffeyville, Iola, Colony, Lawrence, and Paola.

Physicians are invited to send to this department items of news of general interest, for example, those relating to society activities, new hospitals, education and public health. Programs should be received at least three weeks before the date of meeting.

University News.—Dr. Vernon E. Wilson, who recently completed his internship in the University of Illinois Research and Educational Hospitals, Chicago, has been appointed assistant dean in charge of student affairs at Kansas University Medical Center, Kansas City. Dr. Wilson, who will also be assistant professor of pharmacology, will assume his new duties Sept. 1.

Personal.—Dr. Lester A. Latimer, who has practiced medicine in Alexander for 43 years, was recently honored by his community at a farewell program in the high school auditorium. The plaque presented to Dr. Latimer in appreciation of his service contains an engraved bronze inscription to Dr. and Mrs. Latimer and a picture of the home that they occupied in Alexander for 25 years and which they are leaving for a new home in Kansas City, where Dr. Latimer will spend his retirement.——Dr. Mowry S. Thatcher of Turon was recently honored with a dinner and program at the Turon High School, given by the community that he has served for over 50 years.——Dr. Samuel T. Coughlin has been elected president of the medical staff of St. Joseph Memorial Hospital, Larned.——Dr. John M. Anderson, superintendent of the Topeka State Hospital, has resigned and will enter private practice in Atlanta.——Dr. Philip A. Bearg has been appointed pediatrician on the staff of the division of maternal and child health, Kansas State Board of Health, Topeka. He previously served as an epidemiologist in the New Haven (Conn.) City Health Department, then was commissioned as passed assistant surgeon in the Public Health Service Reserve Corps, and assigned to the California State Department of Health from 1943 to 1945, when he became health officer of San Luis Obispo, Calif.——Dr. Karl A. Menninger, Topeka, director of education for the Menninger Foundation, was recently honored by the Topeka Chapter of the National Conference of Christians and Jews as the Topekan who had contributed notably to the cause of world brotherhood. The annual citation was presented at the Brotherhood Banquet.

MARYLAND

Dr. Reed Named Hopkins President.—Lowell J. Reed, Ph.D., whose retirement as vice-president of the Johns Hopkins University and Hospital was recently announced (*J. A. M. A.* **152:**1347 [Aug. 1] 1953), has reconsidered his decision to retire and has accepted appointment as president of the university to succeed Detlev W. Bronk, Ph.D., who has been appointed president and chief executive officer of the Rockefeller Institute for Medical Research in New York. In announcing Dr. Reed's appointment, Mr. Carlyle Barton, president of the board of trustees, said: "Dr. Reed's part in developing the present programs of the university, his long association with the faculties and his achievements as a teacher, scientist, and administrator assure us that during his incumbency the university will make steady progress toward the educational and research objectives that have guided it since its founding. These have taken on a new timeliness as interpreted by Dr. Bronk and we are determined to accomplish their substantial fulfillment. . . . In view of Dr. Reed's long and fruitful service to the university, the trustees are particularly grateful for his willingness to assume these further responsibilities at a time when he might rightfully expect to be free of heavy administrative duties."

MASSACHUSETTS

Crippled Children's Clinics.—Consultation clinics for crippled children have been scheduled for Greenfield, Aug. 6, Dr. Charles L. Sturdevant, Boston; Lowell, Aug. 14, Dr. Albert H. Brewster, Boston; and Fall River, Aug. 24, Dr. David S. Grice, Boston.

Alvarenga Prize to Dr. Moore.—On July 14 the College of Physicians of Philadelphia awarded the Alvarenga prize for 1953 to Dr. Francis D. Moore, surgeon-in-chief, Peter Bent Brigham Hospital, Boston, and Mosely Professor of Surgery, Harvard Medical School, Boston, for his outstanding contributions to the knowledge of the changes in body metabolism following surgery. The Alvarenga prize was established by the will of DaCosta Alvarenga of Lisbon, Portugal, an associate fellow of the College of Physicians of Philadelphia, to be awarded annually by the college on the anniversary of his death, July 14, 1883.

MICHIGAN

Fluoride Treatments for Children.—In a special program carried on by the public health dentistry section of the Michigan Department of Health in cooperation with local dentists and health, school, and civic groups, between 16,000 and 17,000 Michigan children, aged 3 to 13 years, are receiving fluoride treatments this summer to prevent tooth decay. The treatments will be given in 116 locations in 27 counties to rural children and to those in areas that do not have fluoride programs during the school year.

Medical Director Appointed.—Dr. James N. Dewane, Menominee, has been named medical director of Libby, McNeill & Libby, food canners, Chicago, to succeed Dr. Roscoe C. Eaton, who retired under the company's pension plan after 38 years' service. Dr. Dewane was previously affiliated with St. Agnes Hospital, Fond du Lac, Wis., and Newton D. Baker General Hospital, Martinsburg, W. Va. He spent two years in military service, attained the rank of captain, and was regimental surgeon of the 11th Constabulary Regiment.

Society News.—The Academy of Surgery of Detroit has elected Dr. Conrad R. Lam, president, Dr. Earl G. Merritt, president-elect, and Dr. Howard T. Howlett, secretary-treasurer. Dr. Roland P. Reynolds, retiring president, was chosen to fill a four year term as councilor.——At the annual meeting of the Detroit Dermatological Society, May 13, Dr. Henry A. Brunsting, Toledo, Ohio, was elected president, Dr. Charles J. Courville, Detroit, president-elect, Dr. Coleman Mopper, Detroit, secretary-treasurer, and Dr. Roy H. Holmes, Muskegon, recorder.

University News.—The University of Michigan Medical School, Ann Arbor, has announced the promotion to full professorship of Drs. A. James French (pathology) and John F. Holt (radiology). Dr. James W. Rae Jr., who has been acting chairman of the medical school's department of physical medicine and rehabilitation, has been named chairman and promoted to associate professor. Dr. Fred M. Davenport has been promoted to associate professorship in the department of internal medicine, school of public health. Also promoted to the rank of associate professor were Drs. Ivan F. Duff and Muriel C. Meyers (internal medicine); Herbert E. Sloan Jr. (surgery); Arthur L. Drew Jr. and Martha R. Westerberg (neurology); Lauren A. Woods (pharmacology); and Robert J. M. Horton (epidemiology). These physicians were promoted to the rank of assistant professor: Drs. Murray R. Abell (pathology), Samuel Behrman (obstetrics and gynecology), Melvin M. Figley (radiology), Everett R. Harrell Jr. (dermatology and syphilology), Willard J. Hendrickson (psychiatry), Robert C. Hendrix (pathology), Robert G. Lovell (internal medicine), and Aaron M. Stern (pediatrics and communicable diseases).

MISSISSIPPI

State Medical Election.—At the annual meeting in Biloxi the Mississippi State Medical Association elected Dr. Monterville Q. Ewing, Amory, president, Dr. Cummings H. McCall, Gulfport, president-elect, Drs. William T. Wilkins, Clarksdale, J. Harvey Johnston Jr., Jackson, and Richard H. Clark, Hattiesburg, vice-presidents, Dr. David S. Pankratz, University, historian, and Dr. Louie T. Carl, Jackson, associate editor.

MISSOURI

Hospital News.—At its annual meeting in St. Louis the St. Mary's Group of Hospitals Alumni elected the following St. Louis physicians as officers: Dr. J. Grey Jones, president; Dr. Carl J. Dreyer, vice-president; Dr. Malcolm B. Bawell, secretary; and Dr. Louis Keller, treasurer.

Personal.—Dr. Norman Tobias, St. Louis, recently addressed a joint meeting of the Buchanan County Medical and Dental Societies at St. Joseph on "Common Diseases of the Mouth." ——Dr. Robert Dean Woolsey, instructor in surgery, St. Louis University School of Medicine, conducted clinics in neurosurgery at the University of Turkey in Istanbul in June. His wife, Dr. Doris L. Woolsey, associate in clinical otolaryngology at Washington University School of Medicine, conducted clinics in otolaryngology at the university.——Dr. John R. Beem, St. Louis, has been appointed staff physician in the medical division of Sharp & Dohme, Philadelphia. Dr. Beem, who left the Army with the rank of captain in 1948, has since been affiliated with the Washington University School of Medicine, St. Louis.

Course in Medicine and Surgery.—The Greene County Medical Society will sponsor a postgraduate course in medicine and surgery, which will be presented by the department of postgraduate medical education of the University of Kansas School of Medicine. The course is planned for afternoon and evening sessions (2½ hours each) the last Wednesday of each month for a six month period beginning in October. It is open to anyone holding the degree of doctor of medicine. A registration fee of $25 is required for the course or $5 for each program (afternoon and evening). At the close of the course a certificate will be issued showing credit for the total hours attended. The tentative schedule of the programs, which will be offered in Springfield, includes a cardiovascular disease seminar and sessions on child psychiatry, hematology, ophthalmology, otolaryngology, chest diseases, medical emergencies, neurosurgery, and plastic surgery.

NEW JERSEY

Newark Honors Dr. Martland.—In recognition of his more than 40 years of outstanding professional service, the Newark City Commission will name the proposed new city hospital in honor of Dr. Harrison S. Martland, Newark, chief medical examiner of Essex County. Dr. Martland, who is professor of forensic medicine at New York University College of Medicine, became pathologist at Newark City Hospital in 1909. He is the holder of the Dr. Edward J. Ill Medal awarded by the Northern New Jersey Academy of Medicine.

NEW YORK

Name Director of Berg Institute.—L. Royal Christensen, Ph.D., assistant professor of microbiology at the New York University College of Medicine, has been appointed director of the new Henry W. and Albert A. Berg Institute for Experimental Physiology, Surgery and Pathology. He has been on the faculty of the college since 1941. The Berg institute was made possible through gifts from the late Dr. Albert A. Berg, who "contemplated a workshop where physiology and pathology would contribute nutriment for the growth of surgery" and whose will provided $500,000 for construction and a fund of well over one million dollars for maintenance of the institute named for him and his brother, the late Dr. Henry W. Berg.

Dr. Larimore Named Deputy Health Commissioner.—Dr. Herman E. Hilleboe, Albany, state health commissioner, has announced the appointment of Dr. Granville W. Larimore, Albany, as deputy health commissioner to succeed Dr. Hollis S. Ingraham, Albany, who was recently appointed first deputy commissioner. Dr. Larimore, who has been director of the Office of Public Health Education, New York State Department of Health, since 1947, is assistant professor of public health and preventive medicine at Albany Medical College and visiting lecturer at Columbia University School of Public Health. He was formerly educational director of the American Cancer Society. During World War II he served in the U. S. Army Medical Corps in which, as chief of the Health Education Unit in the Army Surgeon General's office, he was responsible for the development and administration of the health education program of the Army. He was awarded both the Army Commendation Medal and the Army Legion of Merit. Dr. Larimore was previously affiliated with the Municipal Contagious Disease Hospital in Chicago and served as assistant section chief in the contagious hospitals section of the Chicago Health Department. Since 1947 he has been consultant in public health education to the U. S. Army Surgeon General.

New York City

Dr. Hinsey to Direct Medical Center.—Joseph C. Hinsey, Ph.D., dean of Cornell University Medical College, has been appointed director of the New York Hospital-Cornell Medical Center to succeed Dr. Stanhope Bayne-Jones, for the past six years president of the joint administrative board of the center, who retired June 30 to become civilian technical director of research of the Army Medical Research and Development Program. Dr. Hinsey, who was also professor of anatomy at Cornell, has been affiliated with Washington University School of Medicine, St. Louis, Northwestern University Medical School, Chicago, and Stanford University School of Medicine, San Francisco. During World War II he served as consultant to the Committee on Neurosurgery of the National Research Council and directed research dealing with nerve injuries and with crash injuries in military airplane accidents. Dr. Hinsey, a past president of the Association of American Medical Colleges, has been chairman of its executive council since 1947. He is a trustee of the Sloan-Kettering Institute and the China Medical Board and a member of the Board of Managers of the Memorial Hospital. Since 1942 he has been a faculty representative on the board of trustees of Cornell University and is associate dean of the Graduate School. Dr. Hinsey served on the Committee on the Survey of Medical Education, which was jointly sponsored by the American Medical Association and the Association of American Medical Colleges in 1948-1953, and as a commissioner on the President's Commission on the Health Needs of the Nation in 1952. He is presently national president of Nu Sigma Nu medical fraternity.

Rockefeller Institute Elects New Officers.—At a special meeting of the board of trustees of the Rockefeller Institute for Medical Research, Detlev W. Bronk, Ph.D., president of Johns Hopkins University, Baltimore, and long a member of the board of scientific directors of the institute, was elected president and, in accordance with the newly revised bylaws, chief executive officer. Dr. Thomas M. Rivers, who was elected a vice-president and director, will assume the executive responsibility for an interim period while Dr. Bronk continues as president of Johns Hopkins. Dr. Rivers, who becomes the third director of the institute since its founding in 1901 under the directorship of Dr. Simon Flexner, succeeds Dr. Herbert S. Gasser (*J. A. M. A.* **152:**1154 [July 18] 1953). Mr. David Rockefeller, Ph.D., formerly president of the institute, was elected to the newly created post of chairman of the combined board, which resulted from a merger of the board of trustees and the board of scientific directors, and Dr. George H. Whipple, Rochester, N. Y., formerly vice-president, was elected vice-chairman of the board. The position of president of the board of scientific directors has been discontinued. Dr. Bronk, who was for 19 years director of the Eldridge Reeves Johnson Foundation for Medical Physics at the University of Pennsylvania, Philadelphia, served as coordinator of research during World War II for the air surgeon of the Army Air Forces and since then has been chairman of the National Research Council and president of the National Academy of Sciences. Dr. Rivers served on three commissions to study acute respiratory diseases in World War I and during World War II was on active duty in the medical corps of the U. S. Naval Reserve, being promoted to commodore in October, 1945. He was in charge of a naval research unit at the Rockefeller Institute Hospital and was the officer in command of Naval Medical Research Unit No. 2, which was stationed on Guam.

OHIO

Society News.—At the annual meeting of the board of directors of the Academy of Medicine of Cleveland, Dr. John H. Budd was elected president and Dr. George L. Sackett, vice-president. Dr. George R. Krause was reappointed secretary-treasurer.

Esophageal Speech Institute.—An institute on teaching and improving esophageal speech will be held Aug. 10 at the Cleveland Hearing and Speech Center, 11206 Euclid Ave., under the sponsorship of the American Cancer Society, National Cancer Institute of Institutes of Health, Office of Vocational Rehabilitation, Cleveland Otolaryngological Society, Cleveland Academy of Medicine, and the Western Reserve University School of Medicine. Surgeons, speech pathologists, and lay persons are invited to attend the sessions. Nonspeaking persons who have had a laryngectomy may attend without charge and may be sent by surgeons, cancer societies, societies for crippled persons, and rehabilitation services.

OREGON

University News.—The Tektronic Foundation of Portland has contributed $26,800 to support the surgery department's pain project and other research programs at the University of Oregon, Portland; $16,000 will be used for the two year salary of a neurophysiologist to work under the direction of Dr. William K. Livingston, head of the surgery department, and $10,800 to support graduate assistants for the next three years who will participate in research headed by John M. Brookhart, Ph.D., head of the physiology department.——Dr. Paul G. Hafner, director of the crippled children's program at the University of Oregon Medical School, Portland, since September, 1946, has resigned to devote full time to the private practice of orthopedic surgery in Vancouver, Wash., where he will be associated with Dr. Joseph H. Gill. Dr. Richard L. Sleeter, Medford, has been named to replace Dr. Hafner, with the rank of assistant professor of pediatrics. Other faculty appointments include Dr. Robert E. Buckmaster, clinical instructor in orthopedic surgery; Dr. Robert E. Rinehart, Wheeler, visiting clinical instructor in medicine; and Dr. Nathaniel D. Wilson, clinical instructor in surgery.——A Fulbright research scholarship to travel and study for six months in Italy has been awarded Dr. Robert S. Dow, associate clinical professor of medicine, University of Oregon Medical School, Portland. He will continue his work on neurophysiological research at the University of Pisa.

SOUTH DAKOTA

Fifty Year Club.—Fifty Year Club pins were recently awarded to Drs. John L. Chassell, Belle Fourche, Arthur S. Jackson, Rapid City, and Theodore F. Riggs, Pierre.

State Medical Election.—At the annual meeting in Rapid City the South Dakota State Medical Association elected Dr. Roland G. Mayer, Aberdeen, president; Dr. Arthur W. Spiry, Mobridge, president-elect; Dr. F. Daniels Gillis, Mitchell, vice-president; and Dr. Geoffrey Cottam, Sioux Falls, secretary-treasurer.

Personal.—Dr. Rezin Reagan, Sioux Falls, has retired after 40 years of practice. His four children, however, continue in medical fields: Dr. Paul C. Reagan will carry on his father's practice; Dr. James L. Reagan is in his first year of internship at Western Pennsylvania Hospital, Pittsburgh; Charles Reagan is an executive director with the U. S. Public Health Service in Spokane, Wash.; and the daughter, Genevieve, is an anesthetist at Sioux Valley Hospital, Sioux Falls. Dr. Reagan has been medical director for the National Reserve Life Insurance Company of Sioux Falls and Topeka, Kan., for 30 years.

TENNESSEE

Society News.—The Tennessee Academy of Preventive Medicine and Public Health, which held its first annual meeting May 20 in Nashville, announces that annual sessions hereafter will be held in conjunction with the annual meeting of the Tennessee State Medical Association. Membership in the academy is limited to diplomates of the American Board of Preventive Medicine resident in Tennessee. Officers of the academy are: Dr. Robert H. Hutcheson, Nashville, president; Dr. Monroe F. Brown, Nashville, vice-president; Dr. John J. Lentz, Nashville, president-elect; and Dr. Paul M. Golley, Chattanooga, secretary-treasurer.

WEST VIRGINIA

Cardiac Problems in Industry.—The Golden Clinic-Memorial General Hospital Association at Elkins will hold a symposium Sept. 7-8, on "The Heart in Industry." The medical panel will be comprised of the following physicians: Dr. W. Frederick Richmond, Beckley, president, West Virginia Heart Association; Dr. Robert P. Glover, president, American College of Cardiology, and clinical professor of thoracic surgery, Hahnemann Medical College and Hospital of Philadelphia; Dr. Donald S. Smith, consulting cardiologist, Fisher Body Division, Pontiac, Mich.; Dr. Edward M. Kline, Cleveland, medical consultant, General Electric Company and member of the Committee on the Cardiac in Industry of the AHA; and Dr. Leonard J. Goldwater, chairman, American Heart Association's Committee on the Cardiac in Industry and professor of occupational medicine, Columbia University School of Public Health, New York. Major labor groups and personnel divisions of industry have been invited to participate. The symposium is open to the medical profession and those directly interested in the rehabilitation problem. Further information may be obtained from Dr. Harold L. Jellinek, Golden Clinic, Elkins.

WISCONSIN

Course in Obstetrics.—The University of Wisconsin Medical School, Madison, will hold a postgraduate course in obstetrics, Sept. 1-3 in the graduate lecture room (426 State of Wisconsin General Hospital). This course, conducted by Dr. John W. Harris, professor of obstetrics and gynecology, will have as guest faculty member Dr. Curtis J. Lund, professor and chairman of the department of obstetrics and gynecology, Rochester (N. Y.) University School of Medicine. Advance registration (limited to 40 registrants) is required; fee, $20. Application for registration should be addressed to Dr. Robert C. Parkin, Coordinator of Graduate Medical Education, University of Wisconsin Medical School, 418 N. Randall Ave., Madison 6.

GENERAL

Vitamin Foundation Grants.—Fourteen new grants to 12 universities and 2 hospitals, for research on vitamins and nutrition, amounting to $69,710, have been announced by Dr. Robert S. Goodhart, scientific director of the National Vitamin Foundation, Inc., New York. These grants bring the total appropriated for research by the foundation since its incorporation in February, 1946, to $704,890.50. The foundation has appropriated more than $135,000 in additional funds for educational and public health purposes.

WHO Publishes Epidemic-Warning Cable Code.—The World Health Organization has announced in Geneva the publication of the first cable code to be used on a world-wide scale for transmitting information on epidemics and quarantine measures. The code will be used, beginning Dec. 1, in WHO's epidemic-intelligence service through which the agency is notified of outbreaks of certain diseases and then broadcasts the information to health authorities. Use of CODEPID, the WHO epidemiological cable code, is said to be restricted to national health authorities and WHO offices.

National Medical Fellowships.—Dr. Nathaniel O. Calloway, Chicago, vice-president of National Medical Fellowships, Inc., and Dr. Franklin C. McLean, Chicago, secretary-treasurer, announce the awarding of $74,075 to 46 Negro physicians and scholars in the medical and related fields for the year 1953-1954. National Medical Fellowships, Inc., formerly Provident Medical Associates, which was organized at the end of World War II, has awarded a total of $337,958 in grants to 146 persons for "improvement of Negro medical practice through the advancement of education and research."

Chronic Illness Planning.—The Commission on Chronic Illness has issued a 48 page mimeographed publication entitled "Welfare Council Activities in Chronic Illness Planning." The report, a summary of information that the commission obtained several years ago from a questionnaire to 124 community welfare councils, describes the efforts of community welfare councils in 70 cities and towns to make plans for meeting the needs created by chronic illness in their communities and gives a detailed discussion of the various methods used for local studies of prevalence and adequacy of facilities. A limited number of copies are available and may be obtained, free of charge, from the commission offices at 615 N. Wolfe St., Baltimore 5.

Theobald Smith Award.—The Theobald Smith Award of $1,000 and a bronze medal, sponsored by Eli Lilly and Company of Indianapolis under the auspices of the American Association for the Advancement of Science, will be given for the ninth time at the Boston meeting in December. The prize is given for "demonstrated research in the field of the medical sciences, taking into consideration independence of thought and originality." Nominations should be sent to Dr. Allan D. Bass, Department of Pharmacology, Vanderbilt University School of Medicine, Nashville, Tenn., before Sept. 15. They should be in triplicate and accompanied by full information concerning the nominee's personality, training, and research work. United States citizens under 35 years of age on Jan. 1, 1953, are eligible.

New Trudeau Societies.—According to the National Tuberculosis Association, three new state Trudeau societies were organized during the fiscal year 1952-1953, bringing to 28 the number of states having medical sections in their state tuberculosis associations. The new societies and their officers are: Nebraska Trudeau Society—Dr. William E. Nutzman, Kearney, president; Dr. Herbert B. Kennedy, Omaha, vice-president; Dr. Stanley E. Potter, Omaha, secretary-treasurer. Oklahoma Trudeau Society—Dr. Richard M. Burke, Oklahoma City, president; Dr. Robert M. Shepard, Tulsa, vice-president; Dr. Mark D. Holcomb, Enid, secretary-treasurer. West Virginia Trudeau Society—Dr. William L. Cooke, Charleston, president; Dr. Hugh S. Edwards, Beckley, secretary-treasurer.

Association of University Anesthetists.—Announcement has been made of the formation of the Association of University Anesthetists. The organization committee included physician anesthetists from the following universities and colleges: Columbia, Harvard, Minnesota, Pennsylvania, Tufts, Vanderbilt, and Wisconsin. Additional anesthetists have been elected from the following medical schools: Albany, Boston, Cornell, Duke, Georgia, Johns Hopkins, New York, New York State, Oregon, Rochester, Texas, Tulane, Washington, Wayne, and Yale. The purpose of the new group is to advance the art and science of anesthesia by encouraging original investigations, by developing methods of teaching, and by such free and informal interchange of ideas as a limited membership and common aims make possible.

Fellowships for Psychiatrists.—The National Foundation for Infantile Paralysis has a number of fellowships available to psychiatrists interested in emotional problems of the physically disabled. Eligibility requirements include two years of graduate training in psychiatry. Financial benefits are based on individual needs. Appointments will be made for one year, subject to renewal. The programs of the fellows should be undertaken in a center concerned with rehabilitation of the physically disabled that has affiliations with an approved department of psychiatry and affords opportunity for work with poliomyelitis patients with respiratory difficulties. The department of psychiatry is to be responsible for supervision and training of the fellows. Information may be obtained from the Division of Professional Education, National Foundation for Infantile Paralysis, 120 Broadway, New York 5.

Jane Coffin Childs Memorial Fund.—The Jane Coffin Childs Memorial Fund for Medical Research has announced that between Oct. 25, 1952, and May 15, 1953, it appropriated $238,480 for support of cancer research projects and fellowships. Of the 19 grants, the largest were: (1) to Dr. Francisco Duran-Reynals, lecturer, department of microbiology, Yale University School of Medicine, New Haven, Conn., $49,500 for the study of the part played by viruses in the genesis of cancer; (2) to Dr. Harris Busch, assistant professor of physiological chemistry, Yale University School of Medicine, New Haven, Conn., $25,950 for investigations on the metabolism of tumors in vivo; (3) to Dr. William W. Winternitz, instructor, and Dr. Cyril N. H. Long, professor, department of physiology, Yale University School of Medicine, $24,000 for investigations on the effect of transplantable tumors on the metabolism of the host (albino rats); and (4) to Dr. Baldwin H. Lucke, professor of pathology, University of Pennsylvania Medical School, Philadelphia, $23,100 for investigations on enzyme patterns in relation to the development and growth of neoplasms and the mechanism of metastasis.

Van Meter Prize Award.—The American Goiter Association offers the Van Meter prize award of $300 and two honorable mentions for the best essays submitted concerning original work on problems related to the thyroid gland. The award will be made at the annual meeting of the association in Boston, April 29 to May 1, 1954, if essays of sufficient merit are presented in competition. A place will be reserved on the program for the presentation of the prize award essay by the author, and the essay will be published in the annual proceedings of the association. Essays may cover either clinical or research investigations, should not exceed 3,000 words, and must be presented in English. A typewritten, double-spaced copy in duplicate should be sent to the Corresponding Secretary, Dr. John C. McClintock, 149½ Washington Ave., Albany 10, N. Y., not later than Jan. 15, 1954.

Cardiac Research Applications.—Dr. Irving S. Wright, New York, chairman of the scientific council, American Heart Association, announces that applications are now being accepted for research awards to be made during the coming year under the joint auspices of the association and its affiliates throughout the country. Applications for research fellowships and established investigatorships should be filed by Sept. 15 and applications for research grants-in-aid no later than Dec. 1. Information and forms may be obtained from the Medical Director, American Heart Association, 44 E. 23rd St., New York 10. The research awards will be available for studies to be conducted during the year beginning July 1, 1954. Established investigatorships ($6,000 to $9,000), which may be extended annually for a five year period, are available to scientists of proven ability who are engaged in a research career. Research fellowships ($3,500 to $5,500), awarded for a one year period, are open to persons interested in research and in an academic career. Grants-in-aid, awarded in varying amounts usually not exceeding $10,000, are made on the basis of specific acceptable projects to experienced investigators working in nonprofit institutions, medical schools, hospitals, and laboratories, who have demonstrated their productiveness or who otherwise give promise of accumulating useful new information.

Lasker Awards in Planned Parenthood.—The annual Albert and Mary Lasker Foundation awards in planned parenthood were recently bestowed on the following three persons. 1. Dr. Herbert Thoms, chairman of the department of obstetrics and gynecology, Yale University School of Medicine, New Haven, Conn., received the award "in recognition of his contribution to marital health and happiness in the related fields of obstetrics, marriage counseling, and treatment for infertility." Dr. Thoms, who pioneered in research and development of methods of natural childbirth and rooming-in for mother and child, founded the first infertility clinic in Connecticut and was a prime mover in organizing the first marriage counseling clinic (at Yale) under medical school auspices. 2. Dr. John William Norton, Raleigh, N. C., state health officer of North Carolina, was given an award "for his far-sighted and energetic leadership in making effective an integrated birth control program in the public health services of North Carolina." Dr. Norton is said to have been a leader in the movement establishing in 1937 the first state-supported birth control clinics in the United States and later guiding the integration of planned parenthood into the program of local health department service in the state's 100 counties. 3. Mrs. Philip W. Pillsbury, immediate past president of the Planned Parenthood Federation, Inc., and now its first vice-president and Executive Committee chairman, received the award "for her unique contribution to the well-being of American family life in our generation."

Society News.—At the annual meeting in New York the Medical Society's Executives Conference elected Mr. Ralph W. Neill, Seattle, executive secretary of the Washington State Medical Society, president; Mr. Charles Lively, Charleston, W. Va., executive secretary of the West Virginia State Medical Association, president-elect; and Mr. William H. Bartleson, Kansas City, Mo., executive secretary of the Jackson County (Mo.) Medical Society, secretary-treasurer.——The American Congress of Physical Medicine and Rehabilitation has appointed a committee for the coordination and integration of physical medicine and rehabilitation in geriatrics, with Michael M. Dacso, New York, as chairman, and Nila G. Kirkpatrick Covalt, Rocky Hill, Conn., Harold Dinken, Denver, Karl Harpuder, New York, and G. Morris Piersol, Philadelphia, as members.——At the annual meeting in Hot Springs, Va., the American Orthopaedic Association elected Dr. Alfred R. Shands Jr., Wilmington, Del., president; Dr. Leo S. Lucas, Portland, Ore., vice-president; Dr. J. Warren White, Honolulu, Hawaii, president-elect; Dr. George O. Eaton, Baltimore, secretary; and Dr. H. Page Mauck, Richmond, Va., treasurer. ——At its annual meeting at the Sheraton-Mount Royal Hotel, Montreal, Canada, May 3-5, 1954, the American Association for Thoracic Surgery will initiate a thoracic surgical forum for the presentation of short papers on current thoracic research, anatomy, and modified surgical techniques. Papers at this session will be limited to 10 minutes (including the showing of lantern slides or other illustrative material) with 3 minutes maximum for the discussion of each paper. Abstracts (200 to 250 words) for the presentation of all papers at the 1954 meeting must be received on or before Jan. 1 and should be labeled "For Forum" or "For Regular Program." Five copies of each abstract should be sent to the secretary of the association, Dr. Paul C. Samson, 2938 McClure St., Oakland 9, Calif.

Dietetic Association Meets in Los Angeles.—The American Dietetic Association will hold its annual meeting at the Shrine Auditorium and Convention Hall, Los Angeles, Aug. 25-28. Dr. James R. Wilson, Secretary, A. M. A. Council on Foods and Nutrition, will report on "Low Sodium Foods and Diets" as part of a program on "Newer Findings in Diet Therapy," which will include "The Intake of Excess Fat and Calories in Relation to the Development of Human Atherosclerosis" by Dr. John W. Gofman, Berkeley, Calif., and "Comparative Effects of Diets Containing Large Amounts of Animal and Vegetable Fat Respectively, upon Serum Lipids in Normal and Abnormal Human Subjects" by Dr. Laurance W. Kinsell, Oakland, Calif. Participating in presentations on "Recent Research" will be Drs. Garnett Cheney, San Francisco ("The Present Status of Vitamin U Therapy in the Dietary Treatment of Peptic Ulcer") and Horace R. Getz, Altadena, Calif. ("What Are the Problems in Feeding the Tuberculous Patient?"). In a public relations program Tuesday evening Dr. Eugene Pumpian-Mindlin, Los Angeles, will have as his topic "If You Please." On Wednesday Dr. Wilton L. Halverson, San Francisco, will present "Bilateral Health Programs in Latin America" as the opening topic for a panel on "Steps Toward Better World Nutrition." Dr. James A. Halsted, Los Angeles, will present the physician's viewpoint in a panel on "Cooperative Approach Aids Medical Therapy" Thursday, 1 p. m., and Dr. Anthony J. Rourke, New York, will discuss teamwork during a panel on "Challenges to You," 2 p. m. Other presentations by physicians include:

Emotional Factors in Child Feeding, John A. Anderson, San Francisco.
The Obesity Problem, Harold I. Harvey, Berkeley.
Newer Concepts in the Treatment of the Diabetic, Samuel Soskin, Los Angeles.
Revisions of the Recommended Daily Dietary Allowances, Robert E. Shank, St. Louis.
Psychological Aspects of Food Faddism, Solon D. Samuels, Los Angeles.

At the annual banquet in the Hotel Statler, Friday, 7 p. m., Dr. Frank R. Bradley, St. Louis, will present the Marjorie Hulsizer Copher award for 1953.

Prevalence of Poliomyelitis.—According to the National Office of Vital Statistics, the following number of reported cases of poliomyelitis occurred in the United States, its territories, and possessions in the weeks ended as indicated:

Area	July 25, 1953		July 26, 1952 Total
	Paralytic Type	Total Cases Reported

LATIN AMERICA

Goiter Survey in El Salvador.—A survey, recently reported, indicates that endemic goiter in school children constitutes a serious public health problem in El Salvador. Based on the examination of nearly 35,000 school children in urban and rural areas, it revealed that 22.8% of 26,400 children outside the capital city had enlarged thyroids. In the capital the incidence was 1.1% for 8,000 children. Glands were considered enlarged if on palpation they were found to be four to five times their "normal" size. Of the total number of goiters, 6.2% were of the clearly visible type. The average iodine content of the salt was 0.22 parts of iodine per 10,000 parts of salt, whereas the recommended ratio for prevention of endemic goiter under ordinary circumstances is 1 part iodine per 10,000 parts salt.

FOREIGN

Course on Allergic Diseases.—A course on allergic diseases, including both theoretical instruction and practical work, will be given Oct. 19-23 at the Propaedeutic Medical Clinic of the Hôpital Broussais, under the direction of Prof. Pasteur Vallery-Radot. The course will include anaphylaxis and allergy; experimental anaphylaxis; respiratory allergy; alimentary allergy; cutaneous allergy; digestive, renal, cardiovascular, and hematological manifestations of allergy; allergy to physical agents; antihistamines; and treatment of allergic conditions. Since enrollment is limited, requests for registration should be addressed promptly to the Propaedeutic Medical Clinic of the Hôpital Broussais, 96, rue Didot, Paris XIV^e.

Seminar in Health Education.—The Central Council for Health Education in England will conduct its annual residential summer school in health education at Royal Holloway College, Surrey, just outside of London, Aug. 10-20, for professional workers in medical, educational, industrial, and welfare services. The program is organized on a group discussion basis, and a social program is also provided. The inclusive fee for tuition and residence is £16 16s. (about $47). Information may be secured from the Medical Director, Central Council for Health Education, Tavistock House, Tavistock Square, London, W.C.1.

CORRECTION

Medical Education Foundation.—The editorial "Medical Education Foundation Reports Progress," which appeared in The Journal July 11, 1953, page 1044, listed Connecticut among the eight leading states in foundation activity. The eight leading states should read in order as follows: Nebraska, Indiana, South Dakota, Vermont, Wyoming, New Hampshire, Colorado, and Delaware.

MEETINGS

American Medical Association: Dr. George F. Lull, 535 North Dearborn St., Chicago 10, Secretary.

1953 Clinical Session, St. Louis, Dec. 1-4.
1954 Annual Session, San Francisco, June 21-25.
1954 Clinical Session, Miami, Florida, Nov. 30-Dec. 3.
1955 Annual Session, Atlantic City, N. J., June 6-10.
1955 Clinical Session, Boston, Nov. 29-Dec. 2.

National Conference on Physicians and Schools, Moraine-on-the-Lake Hotel, Highland Park, Ill., Sept. 30-Oct. 2. Dr. W. W. Bauer, 535 N. Dearborn St., Chicago 10, Director.

Public Relations Institute, Drake Hotel, Chicago, Sept. 2-3. Mr. Leo E. Brown, 535 North Dearborn St., Chicago 10, Director.

American Association of Obstetricians, Gynecologists and Abdominal Surgeons, The Homestead, Hot Springs, Va., Sept. 10-12. Dr. William F. Mengert, 2211 Oak Lawn Ave., Dallas, Texas, Secretary.

American Association for the Surgery of Trauma, Drake Hotel, Chicago, Oct. 1-3. Dr. James K. Stack, 700 North Michigan Blvd., Chicago, Secretary.

American Congress of Physical Medicine, Palmer House, Chicago, Aug. 31-Sept. 4. Dr. Walter J. Zeiter, 30 North Michigan Ave., Chicago 2, Executive Director.

American Dietetic Association, Los Angeles, Aug. 24-28. Miss Ruth M. Yakel, 620 N. Michigan Ave., Chicago 11, Executive Secretary.

American Electroencephalographic Society, Commander and Continental Hotels, Cambridge, Mass., Aug. 17-22. Dr. John A. Abbott, Massachusetts General Hospital, Boston 14, Secretary.

American Hospital Association, San Francisco, Aug. 31-Sept. 3. Mr. George Bugbee, 18 East Division St., Chicago 11, Executive Director.

American Medical Writers' Association, Elk's Club, Springfield, Ill., Sept. 23. Dr. Harold Swanberg, 510 Maine St., Quincy, Ill., Secretary.

American Roentgen Ray Society, Netherland Plaza, Cincinnati, Sept. 29-Oct. 2. Dr. Barton R. Young, Germantown Hospital, Philadelphia 44, Secretary.

American Society for Pharmacology and Experimental Therapeutics, Fall Meeting, Yale University, New Haven, Conn., Sept. 7-9. Dr. Carl C. Pfeiffer, 1853 West Polk St., Chicago 12, Secretary.

Biological Photographic Association, Hotel Statler, Los Angeles, Aug. 31-Sept. 3. Miss Jane H. Waters, 533 West 57th St., New York 19, Secretary.

Colorado State Medical Society, Savoy Hotel, Denver, Sept. 29-Oct. 2. Mr. Harvey T. Stethman, 835 Republic Bldg., Denver 2, Executive Secretary.

Gerontological Society, Mark Hopkins Hotel, San Francisco, Aug. 25-27. Dr. Nathan W. Shock, Baltimore City Hospitals, Baltimore 24, Secretary.

Gulf Coast Conference on Industrial Health, Shamrock Hotel, Houston, Tex., Oct. 1-3. Dr. Sidney Schnur, 411 Medical Arts Bldg., Houston 2, Tex., Vice Chairman.

Kansas City Southwest Clinical Society, Kansas City, Mo., Sept. 28-Oct. 1. Dr. W. H. Algie, 825 North 7th Street, Kansas City, Kans., Secretary.

Kentucky State Medical Association, Brown Hotel, Louisville, Sept. 22-24. Dr. Bruce Underwood, 620 South Third St., Louisville 2, Secretary.

Michigan State Medical Society, Pantlind Hotel and Civic Auditorium, Grand Rapids, Sept. 23-25. Dr. L. Fernald Foster, 606 Townsend St., Lansing 15, Secretary.

Mississippi Valley Medical Society, Springfield, Ill., Sept. 23-25. Dr. Harold Swanberg, 510 Maine St., Quincy, Ill., Secretary.

Montana Medical Association, Northern Hotel, Billings, Sept. 17-20. Mr. L. R. Hegland, 104 North Broadway, Billings, Executive Secretary.

National Medical Association, Nashville, Tenn., Aug. 10-14. Dr. John T. Givens, 1108 Church St., Norfolk 10, Va., Executive Secretary.

Neurosurgical Society of America, The Broadmoor, Colorado Springs, Colo., Sept. 23-27. Dr. C. D. Hawkes, 22 North Manassas St., Memphis 5, Tenn., Secretary.

Nevada State Medical Association, Carter Hotel, Elko, Sept. 24-26. Dr. William A. O'Brien III, 505 Chestnut St., Reno, Secretary.

Northern Minnesota Medical Association, Fergus Falls, Aug. 28-29. Dr. C. L. Oppegaard, Crookston, Secretary.

North Pacific Society of Internal Medicine, Harrison, B. C., Sept. 18-19. Dr. Clarence C. Pearson, 1115 Terry Ave., Seattle 1, Wash., Secretary.

North Texas-Southern Oklahoma Fall Clinical Conference, Wichita Falls, Texas, Sept. 16. Dr. C. H. Wilson, 1300 Eighth St., Wichita Falls, Texas, Secretary.

Pennsylvania, Medical Society of the State of, William Penn Hotel, Pittsburgh, Sept. 21-24. Dr. Harold B. Gardner, 230 State St., Harrisburg, Secretary.

Regional Meetings, American College of Physicians:

North Dakota, Fargo, Sept. 12. Dr. Robert B. Radl, 221 Fifth St., Bismarck, Governor.

Arkansas-Oklahoma, Tulsa, Okla., Sept. 19. Dr. Wann Langston, 117 North Broadway, Oklahoma City 2, Governor.

Society of American Bacteriologists, Palace Hotel, San Francisco, Aug. 10-14. Dr. John H. Bailey, Sterling-Winthrop Research Institute, Rensselaer, N. Y., Secretary.

Southwestern Surgical Congress, Hotel Utah, Salt Lake City, Sept. 21-23. Dr. C. R. Rountree, 1227 Classen St., Oklahoma City 3, Secretary.

Tennessee Valley Medical Assembly, Read House Hotel, Chattanooga, Sept. 28-29. Dr. William G. Stephenson, 612 Medical Arts Bldg., Chattanooga 3, President.

U. S. Chapter, International College of Surgeons, Waldorf-Astoria, New York, Sept. 13-17. Dr. Karl Meyer, 1516 Lake Shore Drive, Chicago 10, Secretary.

Utah State Medical Association, Salt Lake City, Sept. 10-12. Dr. Homer E. Smith, 42 South Fifth East St., Salt Lake City 2, Secretary.

Washington State Medical Association, Olympic Hotel, Seattle, Sept. 13-16. Dr. Bruce Zimmerman, 338 White-Henry-Stuart Bldg., Seattle 1, Secretary.

EXAMINATIONS AND LICENSURE

BOARDS OF MEDICAL EXAMINERS

Alaska:* Anchorage and Juneau, Sept. 7. Sec., Dr. W. M. Whitehead, 172 South Franklin St., Juneau.

Arizona:* Phoenix, Oct. 24. Ex. Sec., Mr. Robert Carpenter, 541 Security Bldg., Phoenix.

Guam: The Commission on Licensure will meet whenever a candidate appears or submits his credentials. Director of Medical Services, Guam Memorial Hospital, Agana.

Montana: Helena, Oct. 5. Sec., Dr. S. A. Cooney, 214 Power Block, Helena.

New Hampshire: Concord, Sept. 9. Sec., Dr. John S. Wheeler, 107 State House, Concord.

New Mexico:* Oct. 12-13, Santa Fe. Sec., R. C. Derbyshire, 227 E. Palace Ave., Sante Fe.

North Carolina: *Reciprocity.* Asheville, Oct. 12. Sec., Dr. Joseph J. Combs, 716 Professional Bldg., Raleigh.

Pennsylvania: *Examination.* Philadelphia and Pittsburgh, July. Act. Sec., Mrs. Margaret G. Steiner, Box 911, Harrisburg.

Texas: Fort Worth, Nov. 12-14. Reciprocity applicants must be completed 30 days prior to the meeting date. Sec., Dr. M. H. Crabb, 1714 Medical Arts Bldg., Fort Worth 2.

Utah: *Examination.* Salt Lake City, July. Asst. Dir., Mr. Frank E. Lees, 324 State Capitol Bldg., Salt Lake City.

Puerto Rico: *Reciprocity.* Santurce, Aug. 4. Sec., Mr. Luis Cueto Coll, Box 9156, Santurce.

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Alaska: On application. Juneau or other towns in Territory as decided by Board. *Reciprocity.* On application. Sec., Dr. C. Earl Albrecht, Box 1931, Juneau.

Colorado: *Examination.* Denver, Sept. 9-10. Sec., Dr. Esther B. Starks, 1459 Ogden St., Denver 18.

District of Columbia: *Examination* Washington, Oct. 19-20. Sec., Dr. Daniel L. Seckinger, 4130 E. Municipal Bldg., Washington.

Oklahoma: *Examination.* Oklahoma City, August 28-29. Sec., Dr. Clinton Gallaher, 813 Braniff Bldg., Oklahoma City.

Oregon: Portland, Aug. 29. Final date for filing application is Aug. 12. Portland, Dec. 5. Sec., Dr. Charles D. Byrne, University of Oregon, Eugene.

Texas: *Examination.* Austin, October. Chief Clerk, Mrs. Sandra Allen, 407 Perry-Brooks Bldg., Austin.

Wisconsin: *Examination.* Madison, Sept. 19. Final date for filing application is Sept. 11. Milwaukee, Dec. 5. Final date for filing application is Nov. 27. Sec., Dr. W. H. Barber, 621 Ransom St., Ripon.

---

* Basic Science Certificate required.

DEATHS

Hardesty, John Frank ⊕ St. Louis; born in Winfield, Mo., Dec. 31, 1887; St. Louis University School of Medicine, 1914; since 1934 associate professor of ophthalmology and since 1950 acting chairman of the department at his alma mater; specialist certified by the American Board of Ophthalmology; member of the American Academy of Ophthalmology and Otolaryngology, American Ophthalmological Society, Southern Medical Association, and the Association for Research in Ophthalmology; formerly medical director of St. Louis Society for the Blind; fellow of the American College of Surgeons; served during World War I; on the medical advisory board of Selective Service during World War II; affiliated with St. Louis City Sanitarium, St. Mary's Group of Hospitals, Missouri Baptist Sanitarium, and Bethesda General Hospital; died June 20, aged 65, of melanoma.

Harris, Isaac Burt ⊕ Columbus, Ohio; born in Batesville, Jan. 15, 1873; Starling Medical College, Columbus, 1900; past president of the Columbus Academy of Medicine; fellow of the American College of Surgeons; joined the faculty at his alma mater, and continued on the staff when in 1914 it became Ohio State University College of Medicine, where he was assistant professor of clinical surgery from 1914 to 1925, and professor of clinical surgery from 1925 to 1946, when he retired with the title of emeritus professor; at one time a member of the city board of health; medical director and from 1915 to 1946 chief of staff at St. Francis Hospital; died in Grant Hospital, June 10, aged 80.

Hiller, Frederick ⊕ Chicago; born in Zittau, Germany, April 20, 1891; Ludwig-Maximilians-Universität Medizinische Fakultät, München, Bavaria, Germany, 1917; associate professor of nervous and mental diseases at Northwestern University Medical School; formerly on the faculty of the University of Chicago; specialist certified by the American Board of Psychiatry and Neurology; member of the American Association of Neuropathologists; on the courtesy staffs of St. Francis and Evanston hospitals in Evanston, Ill., and Passavant Hospital; on the staff of the Wesley Memorial Hospital; died in Evanston, Ill., June 28, aged 62, of coronary occlusion.

Wiggers, Herbert August ⊕ New York City; born in New York Sept. 26, 1907; McGill University Faculty of Medicine, Montreal, Canada, 1934; certified by the National Board of Medical Examiners; specialist certified by the American Board of Psychiatry and Neurology; member of the American Psychoanalytic Association and the American Psychiatric Association; secretary of the New York Psychoanalytic Society; treasurer of the New York Psychoanalytic Institute, where he taught at the School of Applied Psychoanalysis; consulting psychiatrist, Towns Hospital; died in Dobbs Ferry, N. Y., June 22, aged 46, of coronary disease.

Dugger, John Wesley ⊕ Jackson, Miss.; University of Tennessee College of Medicine, Memphis, 1915; past president of the Mississippi State Medical Association; member of the American Public Health Association; for many years director of the division of hygiene and factory inspection, state board of health; served as director of Pearl River County Health Unit, Marshall County Health Department, and the tricounty health district composed of Lawrence, Jefferson Davis, and Covington; died in Gulfport, June 2, aged 68, of acute coronary occlusion and myocardial infarction.

Bell, Edward, St. Louis; Meharry Medical College, Nashville, Tenn., 1916; died June 8, aged 62, of cerebral hemorrhage.

D'Amato, Charles Richard ⊕ East Rutherford, N. J.; Georgetown University School of Medicine, Washington, D. C., 1936; served during World War II; school physician; resident in radiology at the Hackensack (N. J.) Hospital; died June 5, aged 42, of coronary thrombosis.

DeMont, Charlotte, Los Angeles (licensed in California in 1917); died May 11, aged 78, of arteriosclerosis.

Dengler, Raymond Archibald, Breiningsville, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1908; on the courtesy staff of Sacred Heart Hospital, where he died June 3, aged 70, of cerebral hemorrhage.

Dill, Wallace Wright ⊕ Norristown, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1900; served on the staff of the Montgomery Hospital; died June 5, aged 76, of a heart attack.

Dunn, Joseph Francis ⊕ Chester, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1908; at one time Delaware County coroner's physician; served on the staff of the Sacred Heart Hospital; founder of the diabetic clinic at Taylor Hospital in Ridley Park; died June 11, aged 69, of pulmonary embolism.

Easom, Jack Johnson ⊕ Carthage, Miss.; Tulane University of Louisiana School of Medicine, New Orleans, 1947; died May 28, aged 33.

Edlow, Ernest S. ⊕ Baltimore; Johns Hopkins University School of Medicine, Baltimore, 1921; died April 25, aged 56, of coronary thrombosis.

Ellsworth, Elmer Harvey, Hot Springs National Park, Ark.; Rush Medical College, Chicago, 1904; died June 2, aged 74.

Epperson, Paul Stenerson ⊕ Milwaukee; Medical College of Virginia, Richmond, 1907; specialist certified by the American Board of Radiology; member of the Radiological Society of North America; formerly assistant clinical professor of roentgenology at Marquette University School of Medicine; served during World War I; affiliated with St. Mary's Hospital; died at Genesee Lake near Oconomowoc, April 30, aged 66, of a heart attack.

Folk, John L. ⊕ Fairfax, S. C.; Medical College of the State of South Carolina, Charleston, 1888; died May 8, aged 86, of coronary thrombosis.

Fowler, Wiliam Robert, Hamilton, Texas; Arkansas Industrial University Medical Department, Little Rock, 1890; died in the Hamilton Clinic & Hospital June 9, aged 85, of coronary occlusion.

Frank, Irving Leslie ⊕ Philadelphia; University of Pennsylvania School of Medicine, Philadelphia, 1937; specialist certified by the American Board of Obstetrics and Gynecology; fellow of the American College of Surgeons; formerly on the faculty of Jefferson Medical College; affiliated with the Jewish Hospital and the Albert Einstein Medical Center; died June 4, aged 38.

Franklin, Abraham Lincoln, Providence, Ky.; Barnes Medical College, St. Louis, 1893; physician for the Louisville and Nashville Railroad; died May 30, aged 85.

Frisch, Frank Peter ⊕ Willmar, Minn.; University of Minnesota Medical School, Minneapolis, 1914; specialist certified by the American Board of Otolaryngology; fellow of the American College of Surgeons; on the staffs of the Willmar Hospital and the Rice Memorial Hospital, where he died March 8, aged 68, of left ventricular failure, coronary sclerosis, cardiomegaly, and leukemia.

Gaberman, David B. ⊕ Detroit; Detroit College of Medicine and Surgery, 1920; affiliated with Florence Crittenton and Brent General hospitals; died June 12, aged 58, of heart disease.

Gellman, Isaac I., Kew Gardens Hills, L. I., N. Y.; Chicago College of Medicine and Surgery, 1914; fellow of the American College of Chest Physicians; served on the staffs of various Veterans Administration hospitals; died June 13, aged 63, of cerebral hemorrhage.

⊕ Indicates Member of the American Medical Association.

Gorr, Charles William, Chicago; Rush Medical College, Chicago, 1903; died in the Grant Hospital June 29, aged 74, of cerebral accident.

Graham, Edwin E. ⊕ Philadelphia; Jefferson Medical College of Philadelphia, 1887; emeritus professor of diseases of children at his alma mater; member of the American Pediatric Society; past president of the Philadelphia Pediatric Society; affiliated with Philadelphia General Hospital; consultant pediatrician at the Training School of Vineland, N. J.; received the honorary degree of doctor of science from Jefferson in 1950; died in Madison, Va., June 10, aged 89.

Gray, Joseph Rea Taylor Jr. ⊕ Chester, Pa.; Hahnemann Medical College and Hospital of Philadelphia, 1898; member of the American Society of Clinical Pathologists; for many years city bacteriologist; affiliated with the J. Lewis Crozer Homeopathic Hospital; died June 9, aged 83, of arteriosclerosis and myocarditis.

Green, Norman Smith, Seattle, Wash.; University of Cincinnati College of Medicine, 1943; member of the Ohio State Medical Association; formerly practiced in Cincinnati, where he was on the staffs of the Bethesda and Deaconess hospitals; died June 4, aged 40.

Hall, Harry Bolander ⊕ Boise City, Okla.; St. Louis College of Physicians and Surgeons, 1921; served as health superintendent of Cimarron County; chief of staff of the Cimarron County Hospital; died in St. Joseph Hospital, Clayton, N. Mex., May 26, aged 61, of occlusion of the basal artery of the brain.

Hall, Hugh Joseph ⊕ Providence, R. I.; Hahnemann Medical College and Hospital of Philadelphia, 1930; died in the Roger Williams General Hospital June 20, aged 56, of arteriosclerotic heart disease and diabetes mellitus.

Hanna, George Orvil, Lingle, Wyo.; Ensworth Medical College, St. Joseph, Mo., 1905; died in Scottsbluff, Neb., May 16, aged 71.

Harrison, Edwin Marriott ⊕ Chicago; Dunham Medical College, Chicago, 1902; Jenner Medical College, Chicago, 1904; Chicago College of Medicine and Surgery, 1909, and Bennett Medical College, Chicago, 1912; fellow of the American College of Surgeons; served during World War I; on the staff of the Illinois Masonic Hospital; died June 24, aged 76, of coronary thrombosis.

Hart, James Luke, Denver; University of Colorado School of Medicine, Denver, 1942; formerly affiliated with the U. S. Public Health Service Reserve; died in June, aged 35.

Hearn, Marion ⊕ Philadelphia; Jefferson Medical College of Philadelphia, 1902; died June 2, aged 78, of coronary thrombosis.

Heise, William Frederick Carl ⊕ Winona, Minn.; Rush Medical College, Chicago, 1896; fellow of the American College of Surgeons; on the staff of the Winona General Hospital; died May 29, aged 77.

Hermance, William Oakley ⊕ Philadelphia; University of Pennsylvania Department of Medicine, 1894; served on the faculty of the Medico-Chirurgical College, Graduate School of Medicine, University of Pennsylvania; formerly clinical professor of proctology at Woman's Medical College of Pennsylvania; member and past president of the American Proctologic Society; specialist certified by the American Board of Proctology; died June 12, aged 80.

Herrick, Fred Samuel, Chicago; Bellevue Hospital Medical College, New York, 1884; died in the Illinois Masonic Hospital June 17, aged 95, of carcinoma of the prostate.

Herrington, Lewis Marion, McKees Rocks, Pa.; Western Pennsylvania Medical College, Pittsburgh, 1901; died in Winter Haven, Fla., May 17, aged 95, of cerebral hemorrhage.

Hervey, James R. ⊕ Moorhead, Miss.; Atlanta College of Physicians and Surgeons, 1902; formerly mayor; past president of the Citizens' State Bank; died May 22.

Higbee, Frank O., Three Oaks, Mich.; the Hahnemann Medical College and Hospital, Chicago, 1894; College of Physicians and Surgeons of Chicago, 1895; served as health officer; died in Gary, Ind., June 5, aged 83, of chronic myocarditis.

Howitt, Henry Orton ⊕ San Rafael, Calif.; Cooper Medical College, San Francisco, 1887; an Associate Fellow of the American Medical Association; died in Everett, Wash., June 8, aged 90, of arteriosclerotic heart disease.

Huff, Asher DeWitt ⊕ Marion, Ind.; Indiana University School of Medicine, Indianapolis, 1932; died April 18, aged 55, of coronary occlusion.

Hussey, Cyril Christopher ⊕ Sidney, Ohio; Johns Hopkins University School of Medicine, Baltimore, 1919; affiliated with Piqua (Ohio) Memorial Hospital and the Wilson Memorial Hospital, where he died May 9, aged 59, of peritonitis and perforated duodenal ulcer.

Ingalls, Albert Thompson ⊕ Los Angeles; Indiana Medical College, School of Medicine of Purdue University, Indianapolis, 1906; died May 1, aged 78.

Lawry, Carl C. ⊕ Earlville, Ill.; Northwestern University Medical School, Chicago, 1903; an Associate Fellow of the American Medical Association; died in Vandalia recently, aged 76, of coronary arterial disease.

Lindley, Don Carlos ⊕ New Castle, Pa.; Jefferson Medical College of Philadelphia, 1901; specialist certified by the American Board of Ophthalmology; served during World War I; on the staffs of the Jameson Memorial and New Castle hospitals; surgeon for the Baltimore and Ohio and Pennsylvania railroads; died May 8, aged 77, of coronary thrombosis.

Little, Abby Noyes ⊕ Laconia, N. H.; Woman's Medical College of Pennsylvania, Philadelphia, 1894; on the courtesy staff of Laconia Hospital, where she died May 28, aged 81, of pulmonary embolism.

Loughead, Raymond B. ⊕ Boothwyn, Pa.; Medico-Chirurgical College of Philadelphia, 1904; died May 14, aged 88.

McGrath, John Henry ⊕ Waterbury, Conn.; Yale University School of Medicine, New Haven, 1908; affiliated with St. Mary's Hospital, where he died June 15, aged 69, of coronary occlusion.

Menown, Roland R. ⊕ St. Louis; Marion-Sims-Beaumont Medical College, St. Louis, 1903; died June 10, aged 72, of coronary thrombosis.

Miles, James Oliver, Washington, D. C.; Howard University College of Medicine, Washington, 1932; during World War II volunteered his services to the Army as an examining physician of inductees and for this work was awarded a medal of recognition by the President; for many years on the staff of the Freedmen's Hospital; died June 14, aged 57.

Montgomery, Alexander ⊕ Milwaukee; Milwaukee Medical College, 1909; fellow of the International College of Surgeons and the American College of Surgeons; affiliated with Johnston Emergency and Evangelical Deaconess hospitals; died June 9, aged 66, of myocardial infarction.

Robinson, Andrew Smith ⊕ Akron, Ohio; Western Reserve University School of Medicine, Cleveland, 1914; specialist certified by the American Board of Internal Medicine; fellow of the American College of Physicians; member of the Industrial Medical Association; served during World War I; affiliated with City, Goodyear, and St. Thomas hospitals; died June 17, aged 63, of cancer of the lungs.

Rouse, Francis Ernest ⊕ Williamsport, Pa.; St. Louis College of Physicians and Surgeons, 1906; also a graduate in pharmacy; died May 8, aged 77.

Ryburn, John Patrick ⊕ St. Louis; National University of Arts and Sciences Medical Department, St. Louis, 1918; member of the American Academy of General Practice; on the staff of the Missouri Baptist Hospital, where he died June 8, aged 59, of coronary thrombosis.

Sansoucy, Jerome Aime ⊕ Washington, D. C.; Georgetown University School of Medicine, Washington, 1936; died June 25, aged 46, of melanocarcinomatosis.

Schuette, William Henry ⊕ Mason City, Ill.; Hering Medical College, Chicago, Homeopathic, 1904; an Associate Fellow of the American Medical Association; died in Memorial Hospital, Springfield, April 10, aged 81, of injuries received when struck by an automobile.

Sheftman, Murray, Yonkers, N. Y.; University and Bellevue Hospital Medical College, New York, 1926; served during World War II; died March 16, aged 50, of acute coronary thrombosis.

Sherwood, Harry ⊕ New York City; New York Homeopathic Medical College and Flower Hospital, New York, 1918; on the staff of the Mount Sinai Hospital; died March 12, aged 62.

Simpson, Carl Franklin ⊕ Tulsa, Okla.; University of Louisville School of Medicine, Louisville, Ky., 1926; secretary-treasurer of the Tulsa County Medical Society for five terms; served as chief of staff of St. John's Hospital; died June 22, aged 53, of coronary occlusion.

Steinfield, Winton ⊕ Yaphank, L. I., N. Y.; University of Pennsylvania School of Medicine, Philadelphia, 1941; member of the Michigan State Medical Society; specialist certified by the American Board of Internal Medicine; served during World War II; formerly on the staff of the Veterans Administration Hospital in Tucson, Ariz.; drowned in Delaware Bay off Cape May, N. J., in April, aged 35.

Swindler, Edwin Booth, Stuttgart, Ark.; Memphis (Tenn.) Hospital Medical College, 1912; died in Coral Gables, Fla., June 20, aged 70, of cerebral hemorrhage.

Thomas, Claude LeRoy, Philadelphia; Hahnemann Medical College and Hospital of Philadelphia, 1901; served on the staffs of Hahnemann Hospital and St. Luke's and Children's Medical Center; died June 5, aged 79, of acute cardiac dilatation.

Thompson, William Edward, Los Angeles; McGill University Faculty of Medicine, Montreal, Canada, 1882; L.R.C.P. and L.R.C.S., Edinburgh, 1886, and L.F.P.S., Glasgow, 1886; died April 4, aged 93, of congestive heart failure.

Treacy, Alfred Joseph M. ⊕ Philadelphia; Temple University School of Medicine, Philadelphia, 1915; specialist certified by the American Board of Physical Medicine and Rehabilitation; served during World War I; member of the American Rheumatism Association; at one time medical officer in the contagious diseases division, city health department; died in Physicians and Surgeons Hospital June 7, aged 72, of chronic myocarditis and uremia.

Turnoff, David ⊕ Philadelphia; University of Pennsylvania School of Medicine, Philadelphia, 1936; specialist certified by the American Board of Internal Medicine; served during World War II; associate in medicine at his alma mater; affiliated with Nazareth, Kensington, and Philadelphia General hospitals; died June 14, aged 41.

Vonnahme, Conrad Benedict ⊕ East St. Louis, Ill.; Washington University School of Medicine, St. Louis, 1905; died in St. Mary's Hospital June 8, aged 72, of hemolytic anemia.

Watts, Stephen Hurt ⊕ Charlottesville, Va.; Johns Hopkins University School of Medicine, Baltimore, 1901; formerly professor of surgery and gynecology at the University of Virginia Department of Medicine; member of the American Surgical Association and Southern Surgical Association; fellow of the American College of Surgeons; died in the University of Virginia Hospital June 7, aged 75, of intraventricular hemorrhage.

Webb, William Thomas, Breckenridge, Texas; Physio-Medical College of Texas, Dallas, 1906; formerly city and county health officer; died May 29, aged 79, of bronchopneumonia.

Whipper, Ionia Rollin, Washington, D. C.; Howard University College of Medicine, Washington, 1903; died April 23, aged 78.

Williams, Frederick Smith, White Plains, N. Y.; Harvard Medical School, Boston, 1903; registrar of records for the Bronx County Health Department from 1912 to 1945; died June 18, aged 78, of a heart attack.

Williamson, Cleburne Milton ⊕ Corpus Christi, Texas; University of Texas School of Medicine, Galveston, 1923; died May 24, aged 59.

Willis, Morton William ⊕ Jamaica, N. Y.; University and Bellevue Hospital Medical College, New York, 1932; assistant clinical professor of medicine at the New York Medical College, Flower and Fifth Avenue Hospitals; specialist certified by the American Board of Internal Medicine; affiliated with Mount Sinai Hospital in New York, Queens General, and Jamaica hospitals; died May 23, aged 45.

Wilson, George Wheeler, Captain, U. S. Navy, retired, Nevada, Mo.; St. Louis University School of Medicine, 1914; entered the Navy Aug. 4, 1920; retired April 1, 1950; on the staff of State Hospital No. 3, where he died June 9, aged 61, of coronary thrombosis.

Wolf, Charles N., York, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1889; died May 15, aged 89, of arteriosclerosis.

Wolfe, Jacob S. ⊕ Bloomfield, N. J.; College of Physicians and Surgeons, Baltimore, 1890; an Associate Fellow of the American Medical Association; formerly member of the board of education and the board of health, of which he was president; affiliated with Mountainside Hospital, Montclair; died in Akron, Ohio, May 17, aged 87, of bronchopneumonia.

Woods, Robert Andrew, Pittsburgh; University of Tennessee Medical Department, Nashville, 1882; died June 22, aged 90, of complications resulting from a fall and a fractured hip.

Zwick, Karl George ⊕ Cincinnati; Medical College of Ohio, Cincinnati, 1903; assistant professor of dermatology and syphilology at University of Cincinnati College of Medicine; specialist certified by the American Board of Dermatology and Syphilology; member of the American Academy of Dermatology and Syphilology; affiliated with Cincinnati General and Deaconess hospitals; died May 30, aged 75.

DIED WHILE IN MILITARY SERVICE

Fidler, Albert John Eugene ⊕ Commander, U. S. Navy, Coronado, Calif.; born in Allentown, Pa., April 24, 1903; St. Louis University School of Medicine, 1929; following completion of his internship at the U. S. Marine Hospital in Staten Island, N. Y., served with the U. S. Public Health Service, and from 1932 through 1942 practiced medicine in Allentown, Pa., where he was a member of the surgical staff of the Sacred Heart Hospital and of the Allentown Hospital; receiving a commission in the medical corps of the Naval Reserve in 1942, reported in May of that year to the Navy Yard Dispensary, Philadelphia, for indoctrination and duty; transferred to the regular Navy in 1946; during his naval career served aboard various ships of the Fleet and at Navy Medical Department facilities throughout the United States; in August, 1952, reported to the Naval Ordnance Test Station, Inyokern, Calif., where he was serving at the time of his death; awarded the European and Asiatic-Pacific Theater Campaign Ribbons, each with one bronze star; died June 12, aged 50, of injuries received in an automobile accident.

Wilde, Roger Conant Jr., Evanston, Ill.; born in Orleans, Vt., Aug. 27, 1927; University of California Medical School, San Francisco, 1951; after interning a year at the University of California Hospital in San Francisco was assistant resident in pediatrics at the same hospital; in October, 1952, was commissioned in the medical corps of the navy and reported for duty at the U. S. Naval Hospital in Oakland, Calif.; after a short tour at the naval base at Litchfield Park, Ariz., was sent to Pensacola, Fla., in April for flight surgeon training; lieutenant (jg) medical corps of the U. S. Naval Reserve; killed in a plane crash near Pensacola, Fla., May 26, aged 25.

GOVERNMENT SERVICES

ARMY

Following is an abstract of a statement from the Army.—ED.

Three Years of Medical Service in Korea.—During the three years of fighting in Korea, the Army Medical Service, with some help from other nations and services, had the task of maintaining the health of and caring for wounded and injured soldiers from some 15 nations of the world.

The primary interest of the Medical Service, however, was the troops of the United States Army who had come from the relatively tranquil life of occupation duty in Japan to fight a series of demoralizing battles in the extreme heat of the Korean summer, the extreme cold of the Korean winter, over frozen ridges, in insect-infested rice paddies, and through monsoons. The problem was aggravated by the hordes of refugees and homeless wanderers who jammed roads and represented a mobile source of infection and disease which was almost impossible to control.

As soon as possible after landing, the Medical Service began forceful campaigns of preventive medicine designed to halt the advance of disease and impress upon the individual soldier the need of taking necessary sanitary measures to protect himself. The result of this campaign is self-evident in the subsequent decline of the disease rates. The preventive medicine program was backed up later by regular medical inspections of troop areas, especially in the rear, to assure that proper sanitary measures were being taken.

Battle Injuries and Wounds.—The rates of occurrence for battle wounds and injuries have been far from constant during the past three years. The peak for battle casualties came in September, 1950, shortly after the offensive which carried UN forces to the Yalu River in Manchuria. At this time there were 1,187 casualties per 1,000 average strength per year. The lowest rate for casualties came in March, 1952, when 22 per 1,000 average strength per year were reported.

The fatality rate of wounded has steadily declined through the years so that now, for the three years in Korea, it has reached an all-time low of 2.3%. This figure represents a considerable drop from the 4.5% of World War II, and the World War I figure of 8.1%, excluding gas casualties.

At the same time, the proportion of wounded and injured men who have been returned to duty has increased from the World War II average of 77 for every 100 casualties admitted to medical facilities to about 88 per 100 casualties admitted. Now, however, instead of separating certain partially disabled men from the service, as was done during World War II, the Army has adopted the policy of placing these men in limited duty assignments as combat instructors, thereby minimizing manpower attrition.

Several other factors involving medical treatment have also played an important role in decreasing the fatality rate and in increasing the number of wounded and injured to be returned to duty. High on the list of factors which contribute to this lowering of mortality are the new biologicals that were available throughout the medical system from the very beginning of this operation.

The Mobile Army Surgical Hospital, an innovation since World War II, has also contributed to the lowered death rate. It brings definitive surgical treatment closer to the front lines than ever before. Recently, one of these units, designed to care for no more than 60 patients at a time, treated its 50,000th patient since the Korean conflict started.

A third factor, related directly to the specialist training program of the Army instituted in 1946, has been the complete staffing of the forward area hospitals with highly qualified surgeons and orthopedists, to an extent probably not equaled in World War II. The presence of the well-organized base in Japan, coupled with adequate air evacuation facilities that brought patients from the forward hospitals to the base hospitals in the shortest possible time, has had a definite influence. The helicopter plays an ever-increasing part in the rapid, smooth, and comfortable evacuation of seriously wounded men from the battalion aid station. The trip to a surgical hospital normally an hour or more away by ground transportation, takes only a few minutes. Helicopter ambulance units under the direct control of the division surgeon also have recently been organized.

Nonbattle Injuries.—The peak of nonbattle injuries occurred during the first winter in Korea. Cold injury—frostbite and trench foot—contributed heavily to the nonbattle casualty rates of admission during these months and was considered one of the major medical problems in Korea.

The first cold injury cases were reported in November, 1950, when the Eighth Army had forced the enemy far into North Korea near the Manchurian border where cold weather had already set in. The troops, however, were equipped with cold weather clothing and, because enemy resistance was light, the incidence of cold injury was relatively low.

When the Chinese Communists entered the war and forced the withdrawal from North Korea, however, cold injury rates soared. Troops fought and lived in temperatures as low as 25 degrees below zero Fahrenheit. Units were cut off and pinned down by enemy action. Troops suffered from exposure, loss of clothing and equipment, and lack of supply and warm meals.

Cold injury incidence reached its peak during December, 1950, when 155.4 cases per thousand average strength per year were admitted to medical facilities. Most of these cases were admitted for frostbite, but trench foot incidence was also high.

The highest monthly rate for nonbattle casualty admissions during the entire Korean campaign occurred during January, 1951, when 352 cases per thousand average strength per year were admitted. Of this number, almost half were for cold injury sustained during heavy defensive action in the Wonju-Suwan area. The remainder can be attributed to accidents involving vehicles and weapons.

To offset the high incidence of cold injury, the Army inaugurated a preventive program in Korea and cold weather indoctrination in the United States in the fall of 1950. Had this not been done, the rate would most certainly have reached more serious proportions. Indoctrination on the use of cold weather equipment was instituted as far down in echelon as company and platoon level.

Since the first winter in Korea, 1950-1951, the incidence of cold injury cases has steadily declined. The peak weekly rate during the 1951-1952 season was 51 cases per thousand average strength per year as against the peak of 293 cases per thousand average strength per year experienced during the first week of December, 1950. The most recent season, 1952-1953 appears to represent a further improvement, with the peak rate at 13.17 cases per thousand average strength per year.

Disease.—Disease has been the greatest enemy of the American soldier in Korea for the past three years, having rendered ineffective many more soldiers than have Communist bullets and weapons. Korea is abundantly infested with insects that spread disease; lice that spread typhus and relapsing fever; fleas that carry endemic typhus; flies that carry intestinal diseases; mites that are suspected of carrying hemorrhagic fever; and mosquitoes that spread malaria. The country has an abundance of rodents that act as hosts to many of the disease-bearing insects. Refuse is generally left lying in piles or thrown into open ditches, while the disposal of waste is extremely primitive.

Korea is a nation in which disease rates reach staggering proportions. Dysentery, diarrhea, and enteritis have long caused severe morbidity. Malaria, venereal disease, and typhus fever are serious problems. Typhoid, leprosy, smallpox, and encephalitis are prevalent.

The success of the preventive medicine program of the Medical Service is attested to by simply comparing the month of August of 1950, 1951, and 1952. In August, 1950, there were 1,394 admissions per thousand average strength per year. This rate was cut by August, 1951, to 571 admissions per thousand strength and to 466 in August of 1952.

Neuropsychiatric Disorders and Treatment.—Based on late World War II experience, neuropsychiatric treatment during the Korean campaign followed three new principles: treatment as far forward as possible, centralization of screening and treatment, and the avoidance of a hospital atmosphere. By following these three principles, experience has shown that 40 to 60% of all combat neuropsychiatric casualties can be returned to duty after treatment on an excused-from-duty basis. The incidence of neuropsychiatric disorders among troops in Korea reached its peak shortly after the hostilities began in 1950 and has declined ever since.

Neuropsychiatric cases in Korea have been classed into five categories: (1) psychoneurotic disorders; (2) character and behavior disorders; (3) diseases of the nervous system; (4) psychotic disorders; and (5) all other psychiatric disorders.

Of the five classifications, that of psychoneurotic disorders has accounted for the greatest proportion of casualties, with 35.9%. Psychoneurosis is the term fitting the anxiety, dissociative, obsessive-compulsive, and depressive behavior patterns. Included in the "all other psychiatric disorders" classification, which accounts for 26.7% of all cases, are combat exhaustion and situational maladjustment. Character and behavior disorders accounted for 18.8% of the cases and is identified by alcoholism, drug addiction, and immaturity reactions. Accounting for 11.9% of all cases were cerebral hemorrhage and diseases of the nervous system such as meningitis, epilepsy and paralysis. Of all neuropsychiatric cases during the Korean campaign, only 11% have been evacuated to the United States.

Evacuation and Mobile Army Surgical Hospital.—While the saving of a great many lives can be attributed to the increased administration of whole blood, two other factors have also helped immeasurably—rapid air evacuation and the Mobile Army Surgical Hospital.

During the three years of the Korean campaign, both helicopters and large transport-ambulance planes have played an extremely important role. The little helicopter, capable of carrying two litter patients and one patient in a sitting position at a time, can go as far forward as a battalion aid station and at times even farther, pick up severely wounded soldiers and quickly fly them to a hospital near the front lines. Without them, a long and often fatal litter haul would be necessary.

The role of the larger aircraft is equally as important as the helicopter. They can take wounded men from field hospitals and in just a few hours make available to them all of the services of a large general hospital. Similarly, in just about two days these large ambulance-transports can fly wounded men from Korea to general hospitals near their homes in the United States. These planes, operated almost continually by the Military Air Transport Service, have carried thousands of men from the combat area to Japan and the United States.

The small Mobile Army Surgical Hospital, a post-World War II development, offers severely wounded men definitive surgery shortly after they have been hurt, often within a few minutes. Located in a division area near the front line, the hospital receives patients by helicopter and ambulance, provides them with immediate surgery, and keeps them until they can safely be evacuated further to the rear.

Originally designed to care for 60 patients at a time, many of these little field hospitals have taken care of hundreds of patients at a time. A typical unit is composed of 14 physicians, 12 nurses, 2 Medical Service Corps officers and 97 enlisted men.

It usually sets up in the field in much the same manner as a circus. In addition to its tentage, the hospital unit carries with it sufficient organic transportation so that it can move itself from place to place without help from another source. This versatile hospital can be dismantled and all of its equipment can be packed and moved from a location in less than three hours. Thirty minutes after arrival at the new location, a patient can be on an operating table undergoing major surgery and the entire hospital can be functioning less than four hours after arrival.

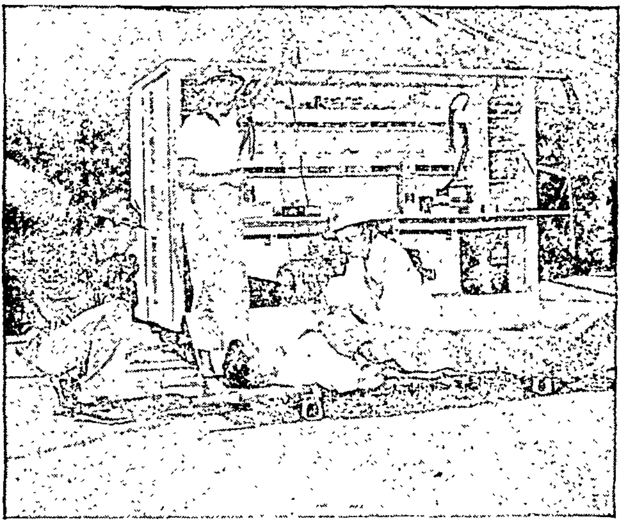
Personal.—Brig. Gen. Sam F. Seeley will soon leave his position as chief of surgery at the Walter Reed Army Medical Center in Washington, D. C., for a new assignment with the Office of the Chief Surgeon, U. S. Army, in Europe headquarters. A graduate of the University of Nebraska and the University of Minnesota Medical School, the general entered the Army in 1927.

NAVY

Personal.—Capt. C. W. Shilling (MC), U. S. N., who has just completed a tour of duty in Washington, D. C., as director of the Research Division of the Navy's Bureau of Medicine and Surgery and as special assistant for Bio Sciences in the Office of Naval Research, is now the senior medical officer at the U. S. Naval Academy, Annapolis, Md. Dr. Shilling was recently awarded the Founder's Medal of the Association of Military Surgeons of the United States for his outstanding contribution to military medicine.——Capt. O. D. Yarbough (MC), U. S. N., a qualified submarine officer, became the director of the Research Division of the Bureau of Medicine and Surgery. Prior to reporting to his present assignment he was force medical officer of the Staff of the Commander, Submarine Force, U. S. Pacific Fleet.——Capt. C. P. Phoebus (MC), U. S. N., reported as special assistant for Bio Sciences at the Office of Naval Research. A qualified naval aviator, prior to coming to his present assignment, Dr. Phoebus was head of the Medical Military Specialties Branch and Aviation Medicine Section of the Research Division of the Bureau of Medicine and Surgery——Capt. Leon D. Carson (MC), U. S. N., the director of the Aviation Medical Acceleration Laboratory at the Naval Air Development Center, Johnsville, Pa., has been appointed a visiting professor of aviation physiology, in the School of Medicine, University of Pennsylvania. He was reappointed as a lecturer in the Graduate School of Medicine in aviation physiology. At the same meeting of the Trustees, Capt. Charles F. Gell (MC), U. S. N., the deputy director of the Aviation Medical Acceleration Laboratory at the Naval Air Development Center, Johnsville, Pa., was reappointed as assistant professor in physiology in the School of Medicine and lecturer in the Graduate School of Medicine.——Dr. Howard T. Karsner, medical research adviser to the Surgeon General of the Navy, has been appointed chairman of the Advisory Medical Board of the Leonard Wood Memorial (the American Leprosy Foundation). In addition to this appointment Dr. Karsner was recently appointed as a member of the Committee on Medical Research of the American Trudeau Society, which is the medical section of the National Tuberculosis Association. Also, he was reappointed as chairman of the Committee on Pathology of the Division of Medical Sciences, National Research Council.

CIVIL DEFENSE

Civil Defense Plant Protection.—The California Civil Defense Organization has been extremely active in preparing industry in the state for enemy attack and for natural disasters. As part of its program of civil defense preparedness, the State Civil Defense Director has encouraged the installation of mobile first aid stations in industrial plants. Patterned after similar units employed with success during World War II in Europe, mobile first aid stations, like the one illustrated, have been built and installed throughout the facilities of the San Diego Consolidated Vultee Aircraft Corporation. The units are kept supplied and ready at all times for possible emergencies. They are also used during civil defense drills, as illustrated.



Mobile first aid station for protection of industrial plants.

PUBLIC HEALTH SERVICE

Water Pollution.—According to the Public Health Service, the nation's municipalities invested about 31 million dollars in water pollution control projects during the first quarter of 1953. Contracts were awarded for 119 sewage treatment projects designed to keep harmful wastes out of rivers, lakes, and other waterways. Of these, 61 are for construction of new sewage treatment plants, 48 for enlargement or improvement of existing plants, and 10 for construction of interceptor sewers.

Local Health Services.—As of July 1, 1952, there were 1,333 health organizations providing full-time local health services in the United States, according to the Public Health Service. These organizations service 1,637 counties, include 279 cities, and cover areas with a combined population of about 120 million. These figures represent an increase over the previous year of 40 organizations, 95 counties, 3 cities, and about 7 million persons with full-time local health services.

Personal.—Dr. Clifton K. Himmelsbach has been appointed assistant chief, Division of Hospitals, Public Health Service, Department of Health, Education, and Welfare. Formerly medical officer in charge of the U. S. Public Health Service Outpatient Clinic in Washington, D. C., Dr. Himmelsbach succeeds Dr. Myron D. Miller, recently assigned as medical officer in charge of the U. S. Public Health Service Hospital, Seattle. As assistant chief of the Division of Hospitals, Dr. Himmelsbach's new responsibilities involve the administration of the 16 hospitals and 125 outpatient facilities that comprise the medical care program for legal beneficiaries of the Public Health Service.

VETERANS ADMINISTRATION

Reorganization.—The reorganization of the Veterans Administration will become effective Sept. 7, 1953, according to acting administrator H. V. Stirling. The three operating officials designated were Adm. Joel T. Boone to continue as chief medical director responsible for the Department of Medicine and Surgery including special services, which was previously a separate operation; Charles G. Beck who will become acting deputy administrator for insurance with responsibility for the reorganized Department of Insurance; and E. E. Odom, now chief legal officer of the Veterans Administration with the title of solictor, who will be the acting deputy administrator for veterans' benefits. As head of the new department the latter will be responsible for all benefit programs including compensation and pension, vocational rehabilitation and education, loan guaranty, guardianship, and contact. Frank W. Kelsey, presently assistant administrator for finance, will be acting controller in the new organization. The budget, audit, accounting, reports and statistics, and policy and planning services will be under his direction. Frank R. Kerr, now assistant administrator for personnel, was designated to fill the new position of acting assistant administrator for administration. He will be in charge of the personnel, purchasing, administrative, and security services. Frank H. Dryden, presently assistant administrator for construction, supply and real estate, will be acting assistant administrator for construction. The only position for which no acting official was designated is the office of general counsel.

Personal.—Managers for the new 1,000-bed neuropsychiatric VA Hospital nearing completion in Salisbury, N. C., and for the existing 200-bed general medical and surgical VA Hospital in Saginaw, Mich., have been appointed. The new hospital in Salisbury will be managed by Dr. Louis F. Verdel, who, since 1944, has been manager of the VA Hospital in Northport, Long Island, N. Y. Dr. Edward H. Mandell, who since April, 1951, has been assistant chief of professional services at the VA Hospital in Minneapolis, becomes manager of the VA Hospital in Saginaw. In addition he will serve as chief of professional services. He succeeds Dr. Morley B. Beckett, recently transferred to the new VA Hospital in Ann Arbor, Mich.

MISCELLANEOUS

Personal.—Dr. Alan T. Waterman, director of the National Science Foundation, has announced the resignation of William A. W. Krebs Jr. as general counsel of the foundation and the appointment of William Jay Hoff, former assistant to the director of the Office of Defense Mobilization and assistant administrator of the Defense Production Administration, to the vacancy.

FOREIGN LETTERS

BRAZIL

Anesthesia in Intrathoracic Surgery.—Dr. Fernando Paulino, head surgeon of the Casa de Saúde São Miguel, published in *Revista Brasileira de Cirurgia* (24:699 [Nov.] 1952) a report on the anesthesia used in 185 consecutive intrathoracic major operations, excluding thoracoplasties and pleurotomies. This is the largest series ever reported in Rio de Janeiro in this field of surgery and does not represent specially selected operations but the total of operations of this kind performed by a specialized surgeon since the founding of that hospital. The total of 185 operations includes 56 cases of pneumonectomy and lobectomy, 32 of esophagectomy and gastrectomy, 40 of thoracolumbar sympathectomy, 25 of exploratory thoracotomy, 3 of mitral valvulotomy, 12 of operations on the esophagus for such conditions as diverticula, atresia, and anastomosis, and 17 others including surgery for mediastinal tumors, diaphragmatic hernioplasty, and pulmonary decortication.

The author discusses the problem of surgical fatality and establishes a distinction between deaths during surgery and those that occur later. A first fact is important: out of the total of 185 patients anesthetized for intrathoracic operations, none died in the operating room. All patients left the operating room in satisfactory general condition and were safely transported to bed. The author points out that the group included patients of less than a month old, a few only two to three days old, and others older than 75; some of the latter had arterial hypertension, cardiovascular lesions, and advanced neoplasms. Dr. Paulino believes that, in the field of intrathoracic surgery, it is an acceptable criterion to include as immediate surgical deaths all those that occur within 10 days after the operation. In this situation, he had eight deaths (4.3%), occurring from four hours to five days after the operation, in cases of atresia of the esophagus, cancer of the esophagus, pulmonary cancer, pulmonary abscess, and hypertension.

In the author's cases all the well-established principles of the technique of anesthesia with tracheal intubation and manually and mechanically controlled respiration were followed. Thiopental (Thionembutal) sodium, nitrous oxide, or nitrous oxide-curare were used for the induction of anesthesia and variable mixtures of ether, oxygen, curare, nitrous oxide, and meperidine (Demerol) hydrochloride for its maintenance. The anesthesia was administered with McKesson's and Heidbrink's apparatus, or with the Espiropulsator and the Pulmoflator. According to the author, the good clinical results cannot be attributed to individual anesthetics or to particular equipment, since these factors varied in different cases, with similar results. He is sure that the three main reasons for the success were (1) the great experience of the anesthetist; (2) the exact blood replacement during the operation; (3) the rigid observance of the physiological principles well established for the compensation of the rupture of the respiratory equilibrium caused by thoracotomy (controlled respiration, tracheobronchial suction, adequate oxygenation and ventilation, and blocking of inconvenient reflexes).

Clinicopathological Study of Pheochromocytoma.—Drs. José Schermann and M. Barretto Netto, of the department of endocrinology, Rio de Janeiro University, reported what seems to be, in the medical literature of Brazil, the first case of pheochromocytoma clinically diagnosed in which surgery was successfully employed and hormonal assays of the tumor obtained. The patient had a typical adrenosympathogenic syndrome with crises appearing under the effect of different kinds of stimulation such as emotions, exertion, prolonged fasting, and abdominal palpation. As complementary symptoms suggesting a chromaffin tissue tumor there were hyperthermia, increase of basal metabolism, and abnormal glycose tolerance, which disappeared after the operation. The histamine test was negative, and the tetraethylammonium chloride test caused a characteristic rise in blood pressure. Particularly helpful for the diagnosis was the perirenal x-ray picture after oxygen insufflation through the presacral space, associated to descendant pyelography, which disclosed a right suprarenal tumor causing a downward displacement of the kidney.

Surgery, with the patient under cyclopropane-curare anesthesia with tracheal intubation, permitted good access through the transpleural route and easy extraction of the tumor. A paroxysmal hypertensive attack occurred during the opening of the pleural cul-de-sac but disappeared spontaneously within a short time. Twice during the postoperative period, a low blood pressure crisis was successfully treated by intramuscular injections of Coramine (a 25% solution of nikethamide) ephedrine, blood transfusions, hydration, Adreno-cortin (an adrenal cortex extract), and strophanthin. The extirpated tumor, weighing 90 gm. and presenting a typical macroscopic aspect, showed at the histological examination characteristic alterations with staining reactions peculiar to the chromaffin tissue. The hormonal analysis of the pheochromocytoma, using von Euler and Hellner's chromatographic method, demonstrated the presence of 2.3 mg. of arterenol per gram of tissue, totaling 207 mg. for the whole tumor. The pharmacodynamic study of the patient's urine showed the presence of 1 mcg. of the hormone per milliliter. Three months after the operation the patient was found in perfect physical condition.

Fatal Hemorrhagic Syndrome in Thoracic Surgery.—Drs. E. Rocha Jr., Isaac Malogolovkin, and E. Marques Tinoco discussed recently two fatal cases of hemorrhagic syndrome, which occurred in a series of 42 intrathoracic operations performed at the Rio de Janeiro Policlinica Geral, representing an incidence of 4.76%. The two fatal accidents are attributed by the authors to a hemorrhagic fibrinolytic afibrinogenemic syndrome. By a careful analysis of the results of the preoperative examinations as well as all the information concerning the operations the authors are sure they can rule out the influence of blood transfusions as well as the possibility of transfusion accidents. Similarly, the absence of coagulability could not be related to an excess of heparin, as it can be deducted from the lack of result of the treatment with protamine sulfate and from the negative result of a later in vitro test. The authors believe that the most probable diagnosis of the cause is massive hemorrhage by afibrinogenemia. They suggest the interference of the liberation, through the lungs, of a fibrinolytic enzyme, acting as a precipitating factor, in consequence of the surgical manipulation.

ITALY

Surgical Transplants.—At the meeting of the Ionic Society of Medicine and Surgery on Dec. 14, 1952, Prof. Paolo Buonsani, the president of the society, read a paper on surgical transplants. It is impossible to replace tissue in man with tissue that is biologically more active or differs greatly histologically. There is a defense reaction by the host tissue against the graft, even against tissues that do not differ greatly although they are more likely to "take." This immunogenic or allergic reaction dooms the graft to eventual replacement by the host's tissues. The incompatibility is less pronounced in autoplastic than in heteroplastic grafts.

The ease with which an avascular transplant takes, as in the cornea and the cartilages, indicates the relative unimportance of the blood supply. In fact, when entire visceral organs are grafted by anastomosis, severe toxicosis of the host results from absorption of the products of decomposition.

The items in these letters are contributed by regular correspondents in the various foreign countries..

Considering that the histopathological process of the graft consists of an inflammatory process similar to the healing of a wound, it can be inferred that the host must first eliminate the necrotic tissue through leukocytic action and then restore the "guide-system" through the lymphocytes. The graft does not regain its neurotrophic capacity.

The former belief that gonadal grafts continue to function must be attributed to the fact that transplanted glands of internal secretion produce a transitory functional or therapeutic effect as a result of catabolic processes, but eventually they become exhausted.

Therefore, it can be said that, although tissues not markedly differentiated from the host tissue give excellent clinical results in grafting procedures, transplantation of vital organs appears difficult. In fact, in the case of arterial transplants they cannot be said to be successful. On the other hand, according to Seddon, the recuperative power of nervous tissue is astonishing.

Sciatica Due to Disk Lesions.—On March 20 Prof. Paride Stefanini, director of the University of Perugia surgical clinic, read a paper at the Rome Medical Academy on the sciatica originating from lesions of the intervertebral disks. Prof. Cesare Frugoni was chairman of the meeting. Professor Stefanini recalled that it was at the Rome Medical Academy in 1941 that he reported on the first two patients with sciatica who recovered after an operation for herniation of the disk. He emphasized that sciatica should not be considered as neuralgia or the pain of neuritis but as the clinical equivalent of a root pain. Its cause may be compression, edema, infiltration, or inflammation, but it can always be demonstrated in essential sciatica. Clinically the radicular origin is demonstrated by the typical root distribution of the spontaneous pain and the paresthesias and disturbances of sensitivity that careful examination almost always reveals in patients with lumbar sciatica. When present, the motor disturbances, which are not too frequent, have a radicular distribution also, while the electrodiagnostic examination reveals a radicular lesion.

Professor Stefanini called attention to the three characteristics of sciatica. 1. It is a disease of one or two roots that usually involves the fifth lumbar and the first sacral roots. 2. The clinical picture does not vary. 3. The patient with sciatica has or has had backaches; sciatica is related to lumbago, just as the sciatic nerve has its origin in the lumbosacral roots. This accounts for the rigidity and the classic defensive position of the trunk in persons with sciatica.

Since the clinical picture is so well defined, it seems probable that the lesion in the lumbosacral roots is constant and characteristic. The question naturally arises of whether sciatica is always due to hernia of the disk. Many authors believe it is; others think that it should be attributed to hernia of the disk only in a certain percentage of cases; others deny this principle and believe that hernia of the disk is a defense of the vertebral column in patients with sciatica. This disagreement of opinions results from the fact that herniation of the disk was not found in every case of sciatica at operation. Professor Stefanini pointed out that degeneration of the nucleus pulposus, cartilages, and annulus occurs in intervertebral disks, especially in the lower part of the vertebral column. Alterations of the intervertebral ligaments may occur in addition to herniation.

Sciatica occurs only when the degeneration is so pronounced that the nucleus pulposus herniates. To support this concept, Professor Stefanini discussed factors that cause him to attribute backache and sciatica to degeneration and hernia respectively. Vertebral pain can also originate in the disk lesion, as can acute sciatica, which can be attributed to sudden protrusions of the disk. Objections to this concept are based on the fact that a trauma is not present in all cases. If previous degeneration is assumed, however, one of the usual and small traumas of every day life would be sufficient to cause protrusion. There is a history of trauma in 50% of the patients with disk hernias, and it is always present in sciatica of sudden onset.

Professor Stefanini refuted the objections based on the negative surgical findings and emphasized the technical difficulties. As for the objection that many patients with sciatica recover with medical treatment, he said that many patients who consider themselves cured or only slightly ill are susceptible to sudden aggravations. On the other hand, even patients who have a definite hernia of the disk often improve spontaneously. These sudden improvements are understandable if it is considered that the pain results not only from compression but also from the effects of other factors (such as infection) that act on the distended root. The role of these other factors may explain why hernia of the disk may be present without pain and that many conditions, such as cold, poisonings, and infections, may erroneously appear to be the cause of sciatica.

Finally Professor Stefanini discussed the principles of selection of treatment for sciatica. Operation should not be performed immediately; in fact, most patients are benefited by medical therapy, bed rest, and physical therapy. When such treatment is not sufficient, a plaster or orthopedic back brace is advisable. In persistent cases surgical treatment should be undertaken. Professor Stefanini reports good or excellent results in about 80% of approximately 200 operations he has performed.

Society of Cardiology.—At a meeting of the Italian Society of Cardiology on March 25, Dr. Boldrini spoke on urinary excretion of riboflavin and the influence of cocarboxylase on the urinary excretion of riboflavin in cardiac decompensation. He had previously observed that administration of digitalis increases the excretion of riboflavin abruptly, while the lactacidemia and pyruremia values rise in an inverse ratio to the riboflavinuria. Since digitalis restricts urinary excretion of thiamine in congestive decompensation, Dr. Boldrini thought that probably in the presence of digitalis the phosphorus radicals with a high energy-producing power are preferably used for the phosphorylation of the thiamine. In other words, he thought that in cardiac decompensation there is also a disturbance in phosphorylation. This hypothesis is supported by the sensitivity of the high blood levels of pyruvic acid found in cardiac decompensation to cocarboxylase and not to thiamine.

To verify the influence of cocarboxylase on urinary excretion of riboflavin, he administered 100 mg. of diphosphothiamine intravenously to six patients with heart disease who were receiving digitalis. The urinary riboflavin values decreased immediately to 70% of the initial values and increased again slowly during the following days. Since this decrease has also been observed in patients with other conditions (such as infectious disease) who were receiving cocarboxylase, Dr. Boldrini believes they also had disturbances of phosphorylation that interfered with the metabolism. Thus, riboflavin that was not utilized was eliminated through the kidneys.

Focal Oropharyngeal Infection and Renal Function.—At a meeting of the Medical and Surgical Society of Pisa, Nov. 21, 1952, Drs. Fiaschi, Grassi, and Andres reported results of their studies of the effect of focal oropharyngeal infection on renal function. They used the sodium thiosulfate clearance rate to determine the rate of glomerular filtration; the sodium para-amino hippurate clearance to measure the renal blood flow and the maximal tubular excreting capacity; and the urea clearance and the endogenous creatinine clearance to measure the tubular reabsorption of water.

The studies were made on 12 patients with oropharyngeal, dental, and tonsillar infection, 7 of whom did not have impairment of the kidney function according to results of an Addis count. The other five patients had signs of acute or chronic glomerulonephritis.

In the seven patients with normal kidney function results of tests for kidney function remained normal after any procedure such as surgical drainage. In the patients with glomerulonephritis, however, any procedure involving the focus of infection was followed by a sudden decrease of glomerular filtration. The changes in the tubular function were much less noticeable. These sudden and pronounced modifications of the glomerular function and kidney circulation were not prevented or even modified by administration of drugs that have a ganglioplegic or sympathicolytic action.

International Symposium on Vitamins.—One of the important recent conventions was held at the Milan Technical Museum where all the astonishing mechanical and technical drawings of Leonardo da Vinci are housed. Luigi Einaudi, president of the Italian Republic, read the inaugural address. Among the foreign representatives were Henrik Dam, Nobel prize winner from the Polytechnic Institute of Copenhagen, W. H. Scopfer, director, University of Bern (Switzerland) Institute of Botany, Georges Mouriquand, director, University of Lyon (France) Pediatric Clinic, and Alfred Vannotti, director, University of Lausanne (Switzerland) Medical Clinic.

Prof. Sabato Vasco, director, National Institute of Nutrition, who was introduced by Professor Colonnetti, president of the National Council of Research, read a paper on the evolution of the concept of vitamins. He said that the vitamins have great biochemical importance and that the action of digestive enzymes depends on the presence of vitamins.

Dr. Aykrod reviewed the history of the discovery of vitamins. Professor Usuelli, director, University of Milan Institute of Zootechny, reported on use of vitamins in animal breeding. Professor Amantea, director, University of Rome Institute of Physiology, reported on the requirements for vitamins in the body.

On the second day, Prof. F. Cedrangolo, director, University of Naples Institute of Medical Chemistry, discussed the biosynthesis of nicotinic acid in animal tissues. He reported on numerous experiments carried out in his laboratory that show that neither tryptophan nor its various metabolites can produce nicotinic acid or pyridine in living tissues or in eggs during incubation. It appears doubtful to him that animal tissues are able to convert tryptophan into nicotinic acid without any bacterial participation.

Prof. P. Di Mattei, director, University of Rome Institute of Pharmacology, discussed the antagonism between drugs that cause avitaminosis and vitamins and the action of vitamins when particular drugs are administered.

Professor Vannotti, Lausanne, Switzerland, reported on vitamins and enzymes from the clinical point of view. The biological action of the vitamins is intimately related to their enzymatic function. Certain vitamins (B complex) differ from the others in that, when they are partially transformed in the organism (by phosphorylation) and joined to a protein, they form cellular ferments and participate as co-enzymes in the regulation of metabolism of carbohydrates, proteins, and fats. Disturbances of the function of these ferments are due to either a deficiency or too great a utilization of the corresponding vitamins or to their insufficient transformation into ferments.

Professor Schopfer, from the University of Bern, reported on antivitamins, which are specific competitive antagonists of the vitamins. Their effect consists in displacing the vitamins, thus hindering the activity of the enzymes of which the vitamins are the co-enzymes. The resultant interference with metabolic processes has repercussions greater than simple displacement: disturbances in the biosynthesis of certain acids, purines, nucleic acids, and other essential metabolic products are increased. In certain micro-organisms it can be shown that not only the specific vitamin corresponding to the utilized antivitamin is displaced but the whole vitamin balance of the organism is disturbed. The avitaminosis caused by an antivitamin is, therefore, apparently similar to that which is secondary to irradiation. While antivitamin avitaminosis does not damage the physiological genotype, avitaminosis due to irradiation does damage the genome.

The point of view presented by Schopfer has great importance. Schopfer compared the effect of antivitamins to avitaminosis due to "mutation" of the enzyme resulting from irradiation that results in cellular inability to synthesize vitamins being transmitted from generation to generation. There is no doubt that this concept will affect the interpretation of some phenomena of enzymatic "deviation" that are typical in cancer. It is known that the enzymatic alterations in cancer are always the same no matter what organ is affected, whereas each healthy organ has its own, different enzymatic system.

Prof. G. Frontali, University of Rome, read a paper on vitamin overdosage. He reported on severe cases of overdosage of vitamin D_2 (300 cases have been reported in the world literature and 17 were fatal), vitamin A (20 cases in the world literature), and vitamin B complex (pronounced toxic manifestations). He proposed that concentrated vitamin preparations be labeled with safe maximal doses and safe intervals between doses. Greater than usual doses should be supplied only on medical prescription.

Henrik Dam, Nobel prize winner, discussed vitamins and antivitamins in blood coagulation. Since 1936 the formation of prothrombin in the body has been known to depend on the supply of vitamin K, and since 1941 to be inhibited by bishydroxycoumarin (Dicumarol). Since 1943 a series of new coagulation factors has been discovered, making modification of the theory of blood coagulation necessary.

Vitamin K and bishydroxycoumarin were originally believed to be simple antagonists. The following observations, however, were incompatible with such a view: Under suitable conditions mixtures of bishydroxycoumarin plasma and plasma deficient in vitamin K coagulate faster than either of the two plasmas alone. In addition, methylnaphthoquinone is almost unable to compensate for the anticoagulation effect of bishydroxycoumarin. The latest theories of blood coagulation and the recent observation that vitamin K_1 compensates efficiently for the action of bishydroxycoumarin have given more ground for the theory of competitive antagonism. Recently it was shown that vitamin K_1 acts much faster than methylnaphthoquinone in simple vitamin K deficiency, and this observation is probably related to the superiority of vitamin K_1 in counteracting the anticoagulant effect of bishydroxycoumarin.

Other papers were read by Professors Chini, from the University of Bari, and Sotgiu, from the University of Rome. Four hundred persons participated in the convention. Among the Americans present was Dr. Clive M. McCay (State College of Agriculture, Cornell University, Ithaca, N. Y.), who read a paper on the evolution of vitamin needs from insects to man.

LONDON

The Queen at the Royal College of Surgeons.—On May 8 the Queen attended a ceremony at the Royal College of Surgeons in London at which she laid a stone containing a casket in which was a Calender of the College and other documents. The president of the college, Sir Cecil Wakeley, welcomed the Queen, and the Bishop of London dedicated the memorial stone. Work on the College of Surgical Sciences (endowed by Lord Nuffield) is to start shortly. The new Great Hall will seat 700 persons and provide a center for surgical congresses, lectures, or social occasions. Above it will be three floors of museums, and departments of anesthesia and dentistry will be provided.

Prescribing Under the National Health Service.—During the first year of the National Health Service, family physicians' prescriptions cost 35 million pounds. This year it is estimated that the cost to the taxpayer will be some 10 million pounds more. Nevertheless, in the summarized accounts of the National Health Services the Auditor-General states that only 282 family physicians were reported for apparent excessive prescribing. All but 11 reduced their prescriptions after a warning "without detriment to the treatment of patients." Now the *British Medical Journal* (1:1040 [May 9] 1953) points out that no departure must be made from recognition of the fact that the physician is the sole arbiter of what is best for his patient.

The Medical Defendant.—A leading article in the *Lancet* (1:887 [May 2] 1953) under this heading draws attention to the fact that medical practitioners are apparently being made the target in increasing numbers of claims based on allegations of negligence. Among the reasons put forward is that it may be an inevitable feature of a health service in which members of hospital staffs are known to be paid. Of course, there is another national service—the free legal aid scheme—in which the plaintiff has access to absolutely free legal aid and advice and loses nothing. Whatever the reason, *Lancet* points out quite correctly that the practitioner, as the menace of writs for damages grows, may be inclined to play for safety when a bold course might help the patient more. The old adage "better a living problem than a dead certainty" may yet become reversed.

Immunization in Diphtheria Outbreak.—In the *British Medical Journal* (1:964 [May 2] 1953) Drs. Lycett and George describe an outbreak of diphtheria that occurred in Staffordshire in 1951. Of 108 patients, 6 died. It was found that the outbreak coincided with a low level of immunity among the child population and the incidence fell after mass immunization, which was accepted willingly by the public confronted with an outbreak of diphtheria. In the 22 severe cases of diphtheria, only 7 patients had been immunized, although none had received a reinforcement dose, and of the patients who died none had been immunized.

The New Year Honors.—The list of medical men awarded honors in the New Year Honour List includes names known all over the world and also names known only in Great Britain. All have deserved this honor, and the public recognition is gratifying to the profession to which they belong. An outstanding man of science and surgeon, Prof. Wilder Penfield enters the Order of Merit, limited in numbers to 24, the two other medical members being Dr. E. D. Adrian and Sir Henry Dale. Professor Penfield was born in America and subsequently became a naturalized Canadian citizen. Before and after the 1914-1918 war he was a Rhodes Scholar at Oxford, where he studied under Sir Charles Sherrington. The titles of his principal publications, "Cytology and Cellular Pathology of the Nervous System," "Epilepsy and Cerebral Localization" (with T. C. Erickson), and "The Cerebral Cortex of Man," show the nature of his contributions to medical science and neurosurgery.

Mount Everest Expedition.—A radical change in the footwear of this year's British Mount Everest expedition is announced. Instead of the familiar heavily nailed, leather climbing boots, the assault parties will wear a much lighter boot with soles of artificial rubber and glacé kid uppers. The boots are insulated inside with a layer of kapok nearly an inch thick. It is pointed out that lightness and warmth are far more important qualities than durability and water-resistance for the Everest assault. The boots, which have already been tried in the Alps, will be required only for a few days' use, and at the temperatures high on Everest water is unlikely to be encountered.

Patients' Charter Seeks Later Hospital Waking.—Later waking is one of many recommendations made in a charter for hospital patients published recently. It is contained in a report to Mr. Macleod, Minister of Health, by the Central Health Services Council. This is a standing body that advises the minister on the National Health Service. Under a lay chairman, Mr. F. Messer, Socialist M.P. for Tottenham, it is composed of representatives of every branch of medicine. "One of the strongest complaints from patients," the report says, "is that the waking hour, apparently without reason, is too early in the morning."

To remedy this, some tasks traditionally performed before physicians' rounds should be done during or after them. "No patients apart from those receiving special treatment should have to be awakened before 6 a. m. and later if possible." Meals should be punctual and suitably spaced. It was not unknown for patients to have nothing between 6:30 p. m. and 8:30 next morning. The unwritten rule that meals should not be served while a physician is visiting a patient should be abolished. There should be a wide choice of food, with both small helpings and second helpings available. A teapot for each patient, with separate milk and sugar, should be the aim.

Hospitals should remember that patients have personalities of their own, and are not merely cases. Since the creation of the National Health Service they have been less willing to accept instructions without question and more responsive to sensible explanations and requests for help. "Medical and nursing staff and administrators should not maintain the attitude of 'theirs not to reason why' which was occasionally adopted towards those dependent on charity or the rates." Voluntary work has a permanent and important place in National Health Service hospitals. "We are glad to see how widely this is recognized."

British Medical Association.—The British Medical Association has this year raised its annual subscription to six guineas ($17.64). In view of what is regarded as the usual effect of such an action on the membership of the association, it is interesting to note the effect. Every year there is a certain number of resignations, which usually fluctuates between 300 and 500; this year it is just over 1,000. But since Jan. 1, 1953, 480 new members have joined, compared with 270 in the same period the previous year.

Physicians Divided Over Practices.—The General Medical Services Committee, which negotiates on fees and conditions for the 20,000 family physicians in the National Health Service, has decided against asking for restoration of the right to buy and sell the good will of practices. Many physicians, notably the 3,000 in the Fellowship for Freedom in Medicine, of which Lord Horder is chairman, believe restoration is essential if defects in the service are to be remedied. Some would make it optional. The committee regards the proposal as impracticable. It will declare itself as not in favor of action along these lines. There is strong feeling on both sides on this issue.

Psittacosis in Britain.—It has long been known that human beings are susceptible to an infectious disease of parrots called psittacosis. The disease is caused by infection with a virus, and in addition to birds of the psittacine group in which parrots, cockatoos, and budgereegahs are included canaries, pigeons, domestic fowls, and ducks all harbor these organisms and have been responsible for infection in man. In 1930, after a serious outbreak of psittacosis, with many deaths, a complete ban was imposed on the importing of parrots into this country. The ban was raised in December, 1951, and it is likely that a number of infected parrots have since been introduced. Indeed, the death on Dec. 4, 1952, of the manager of a pets' corner in a department store was shown at the inquest at Birmingham to be caused by psittacosis acquired from infected parrots in a consignment of birds that he had received in November.

TURKEY

Ascarides Perforated Intestines.—In volume 10 of *Bursa Klinik* Dr. Feridun Timur, chief of the Kutahya General Hospital medical department, reports a case of perforation of the intestines caused by ascarides with resultant peritonitis. The patient, a 30-year-old farmer, had suffered acidity of the stomach, profuse salivation at night, and itching of the nose for five years. Twelve days prior to admission to the hospital the patient felt an abdominal pain that gradually increased; constipation, nausea, and vomiting began, and the pain in the abdomen became unbearable. On admission to the hospital the patient was in a coma and had a temperature of 38.5 C, a pulse rate of 130, hallow cheeks, and a greatly distended abdomen. The blood cell count revealed 3,400,000 red blood cells and 6,000 white blood cells. The differential count revealed 70% polymorphonuclear cells, 21% lymphocytes, 5% transitionals, and 4% monocytes; the sedimentation rate was 32 mm. after one hour; and urinalysis did not reveal anything abnormal. Laparotomy under thiopental (Pentothal) sodium anesthesia was performed by hospital chief surgeon Dr. Osman Dirim. The abdominal cavity revealed seropurulent liquid and at the end of the ileum, about 50 cm. above the ileocecal valve, a 5 mm. perforation. Other than intestinal hyperemia there were no pathogenic conditions of the intestines. One Ascarid micro-organism was about to pass through the perforation into the peritoneum where several more ascarides were found. Palpation revealed the presence of ascardes in the intestines, but the intestinal passage was free. The abdominal cavity liquid did not reveal ascarides eggs. The intestinal perforation was closed with nonaborbable surgical suture, and a large tube was inserted into the abdomen. Recovery, after 25 days, was uneventful.

Tuberculosis Among Primary School Children.—In *Bursa Klinik*, volume 10, Dr. Neshati Üster, chief of the tuberculosis hospital, his associate Dr. Reha Zeybeker, and Dr. Celil Uygun have published the results of their five year investigation concerning BCG prophylaxis and tuberculosis among primary school children of Bursa City. Twenty-eight schools with 8,800 children were investigated. Tuberculin tests resulted in 21.6% to 61.4% positive reactions. The first grade, 6-year-old children had positive Pirquet reactions in 21.6% of the cases, the 7-year-olds 27.2%, the 8-year-olds 31.4%, the 9-year-olds 37.1%, the 10-year-olds 41.5%, the 11-year-olds 43.2%, the 12-year-olds 49.8%, the 13-year-olds 55.3%, the 14-year-olds 61.4%, and the 15-year-olds 60%. Of 5,139 boys 39.5% had positive Pirquet reactions, and of 3,661 girls 37.5% had positive reactions. According to the grades, positive reactions were found as follows:

Grade	No. of Examinations	Percentage of Positive Reactions
First	2,717	21.8
Second	2,106	31.2
Third	1,707	41.4
Fourth	1,325	46.6
Fifth	915	48.0

Of 395 girls given radiographic and clinical examinations 14 (3.5%) had active tuberculosis and 9 (2.3%) had old lesions; of 487 boys 16 (3.3%) had active tuberculosis and 6 (1.25%) had old lesions. Living standards of these children were excellent in two, good in four, fair in nine, poor in six, and very poor in nine. Tuberculosis infection is high among primary school children of Bursa City. At the 11th National Medical Congress, Prof. Nusret Karasu, of the department of phthisiology at Ankara University, reported that tuberculosis infection among primary school children in Turkey is 1.25 to 4.85%.

Antibiotics in Ophthalmology.—In *Göz Klinigi*, the Istanbul periodical for ophthalmology, volume 11, Dr. Nuri Fehmi Ayberk, medical director of the Istanbul-Haydar Pasha General Hospital and chief of the department of ophthalmology, reported his observations concerning antibiotics, anticoagulants, sulfonamides, cortisone, and tissue therapy in ophthalmology. Very good results have been obtained with streptomycin. While a 28-year-old man was under treatment for lung tuberculosis at a sanatorium a solitary tuberculum, the size of a pea, developed in his left eye. The patient was given 20 gm. of streptomycin, and the tuberculum gradually decreased and completely disappeared after a month. Tuberculous meningitis was thus forestalled. In a 30-year-old woman who had previously had spondylitis a tumor developed, the size of an almond, over the bulbar conjunctiva of the left eye. Biopsy revealed uveal lesions and the origin of the tumor to be tuberculosis. The patient was given 15 gm. of streptomycin, and the tumor decreased.

During the trachoma campaign work in the southeastern provinces excellent results were obtained with oxytetracycline (Terramycin). Subjective and objective amelioration resulted in from five to six days in patients with acute and complicated trachoma. Secondary infections, pain, and prolific aqueous humor decreased, and follicular hypertrophy of the conjunctiva diminished, but the trachoma virus did not completely disappear.

In 20 patients excellent results have been obtained with cortisone. A 19-year-old woman had parenchymatous keratitis in the left eye and vision of 1/10; her Wassermann and Kahn tests gave 3+ reactions. The patient was given 1 drop of a 1% cortisone solution three times a day for 10 days, the keratitis disappeared, and vision reverted to 8/10. A 28-year-old man had parenchymatous keratitis in the right eye, vision of 1/10, and a Wassermann test reaction of 3+. After 10 days of therapy with a 1% cortisone solution of one drop three times a day, the corneal infiltration subsided and vision became 5/10. This therapy in both patients was followed by penicillin and bismuth therapy. A 26-year-old man with iritis of undetermined origin in both eyes and negative Pirquet and Wassermann reactions recovered completely after 10 days of cortisone therapy; his vision became 9/10. A 47-year-old woman had subacute hypertensive iritis and lesions in both eyes; her right eye vision was 1/20 and her left eye 5/10. After 15 days of cortisone therapy vision of the right eye was 2/10 and that of the left eye was normal.

In purulent cases very good results have been obtained with penicillin. Of his many such cases Dr. Ayberk cites two. A 14-year-old boy had a furuncle of 15 days' duration over the brow of the left eye, edema then occurred. On admission to the hospital the boy was unconscious, at times he became excited, and he had a temperature of 40 C. The left eyelid and left side of the face were swollen and inflamed; examination revealed chemotic bulbar conjunctiva and exophthalmos of the left eye; the cerebrospinal fluid was cloudy and the pressure was 50 mm. of water; the Pandy test reaction was 4+, and the albumin and cells had increased. A diagnosis of cavernous sinus thrombophlebitis was made. The patient was given 800,000 units of penicillin for five days. The temperature reverted to normal; the patient's general condition improved; and infiltration, inflammation, and edema completely subsided. A 25-year-old woman had a severe headache accompanied by loss of vision in both eyes 20 days prior to admission to the hospital. Clinical and laboratory investigations revealed an optochiasmatic arachnoid. The pupils of both eyes were edematous. The patient, refusing an operation, was given 1 million units of penicillin for 10 days, with the result that the patient, who on admission could discern movement of fingers only at 10 cm., had attained a vision of 6/10, and the patient insisted on being discharged. When she returned three months later vision had reverted to its former low level. The patient again refused surgical intervention. There was no chiasmatic inflammation, but the optic nerve had become atrophic; so the second series of penicillin therapy did not benefit the patient. Penicillin has proved to be a valuable adjunct in the therapy of ophthalmologic diseases. Formerly purulent infections resulted in blindness in 15 to 20%, but the sulfonamides and penicillin have reduced it to 0.5%.

Fifteen patients with hypertension were given heparin or bishydroxycoumarin therapy. Dr. Ayberk cites the following cases: A 40-year-old woman with hypertension of 19/11 suddenly lost vision in the left eye five days prior to admission. Examination revealed thromboangiitis obliterans of the venae centralis retinae. The patient was given heparin, 150 mg. intravenously, daily for one week. Vision soon improved. After 15 days the patient attained a vision of 7/10. A 48-year-old bookbinder, while at work, suddenly lost complete vision in the right eye. Examination at the hospital a few hours later revealed hypertension of 20/12 and thromboangiitis obliterans of the venae centralis retinae in the right eye, he could see the movements of fingers a few centimeters away only. The patient was given heparin, 100 mg. intravenously. On the sixth day the patient had 6/10 vision. A 63-year-old patient with the same diagnosis and 19/10 hypertension was given 100 mg. of heparin intravenously for six days and attained a vision of 6/10. Formerly such patients were doomed to blindness. With anticoagulants, antibiotics, sulfonamides, cortisone, and tissue therapy it can now be forestalled. More than 30 patients, men and woman, 20 to 40 years old, who had retinitis pigmentosa, many of whom had night blindness, and who had vision of 1/10 to 1/50, were given placental grafts and had their vision restored to from 4/10 to 9/10. Patients who had retinopathy also benefited greatly by placental graft therapy.

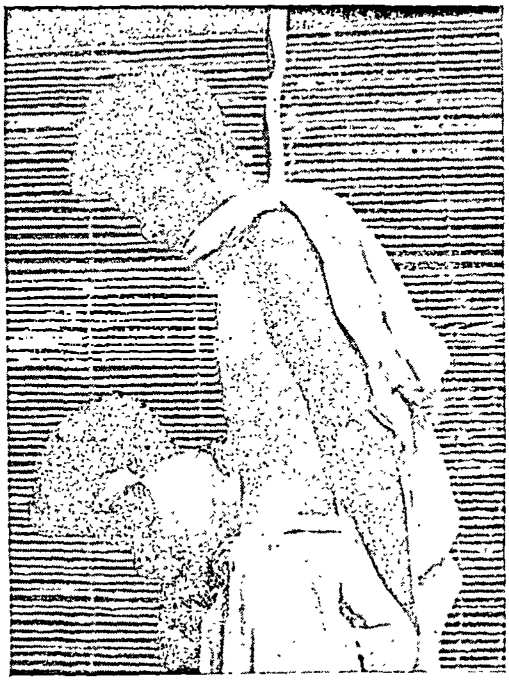
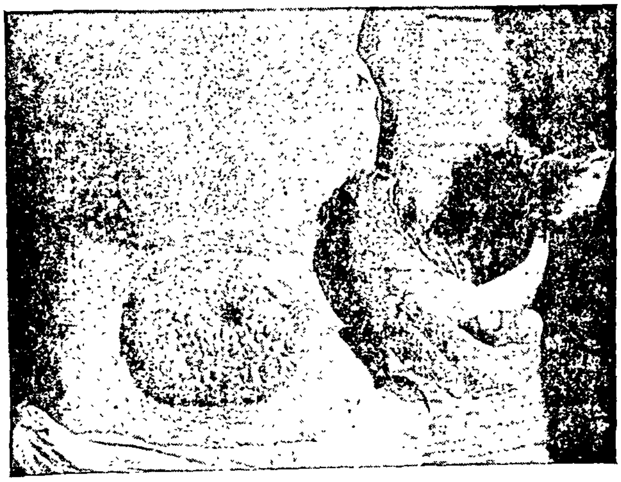
HOME TREATMENT

To the Editor:—One sees some unusual and amusing things in India. One afternoon a 32-year-old Caucasian (East Indian) man walked into the Giffard Mission Hospital. The mouth of a brass pot (a chimboo) was very firmly fixed to his anterior abdominal wall; in fact, a portion of the wall was inside the pot.



The patient had had a stomach-ache and had asked a neighbor's advice as to treatment. The neighbor advised that he take a chimboo (a round, 6-inch, brass pot with a 2-inch mouth), fill it half full of fresh cow dung, heat this well, and then put the mouth of the pot against his abdomen where the pain was. This, the neighbor said, would draw out the pain.



This sounded sensible to the man, so he proceeded to do it. After the pot had been in place for an hour or so, he tried to remove it, but it would not come off. He pulled; some of his friends pulled; but still the pot would not come off. After some thought they came to the conclusion that a vacuum inside the pot was holding it so tightly in place; therefore, if they went to the goldsmith and had him punch a hole in the bottom of the pot, the vacuum would be broken and the pot would surely come off. The goldsmith punched quite a liberal hole in the bottom of the pot, but still it would not come off.

The group then decided that the man should go to the Giffard Mission Hospital. A not-too-serious consultation was held, and the conclusion was reached that we should operate. We borrowed a pair of side-cutting pliers from the business manager and then cut away the pot. The appearance of the abdomen after removal of the pot can be seen in the second illustration. The paraumbilical area was edematous and greatly thickened. When the patient was trying to pull it out through the narrow neck of the pot it was the same as trying to pull a mushroom through a wedding ring. The abdominal wall was badly burned (second degree) from the hot contents of the pot. The patient stayed in the hospital for 10 days while the area healed. During that time he did not complain of abdominal pain so we assume that his home treatment was quite effective.

HYDROCORTISONE (COMPOUND F) FREE ALCOHOL OINTMENT

To the Editor:—In a recent article in The Journal (151:468 [Feb. 7] 1953), we reported that the topical application of hydrocortisone acetate ointment was of value in the treatment of particular diseases of the skin. Our conclusions were drawn after comparing the effects of hydrocortisone acetate in various ointments applied to the affected areas of one side of the body with the effects of the respective ointment base, without hydrocortisone acetate, applied as a control to symmetrically situated affected sites. Observations on 62 patients were included in our first report.

Because oral administration of the free alcohol is more effective than administration of hydrocortisone acetate, we thought it important that ointments incorporating the free alcohol be compared with ointments containing the acetate. The clinical evaluation of the therapeutic effectiveness of the hydrocortisone free alcohol ointment was accomplished by comparing it with the hydrocortisone acetate ointment (incorporated in the same base and in equal concentration) used on the contralateral affected sites of the same patient. Forty patients with various dermatoses were studied. In 17, the hydrocortisone free alcohol ointment proved to be slightly more beneficial than the hydrocortisone acetate ointment. In 18, the hydrocortisone free alcohol and the hydrocortisone acetate ointments were of equal benefit. In the remaining five, the response was slightly better to the hydrocortisone acetate than to the free alcohol ointment. Our comparisons indicate that the clinical benefits from the topical use of ointments containing hydrocortisone free alcohol in selected dermatoses are, to say the very least, equal to those obtained from the use of hydrocortisone acetate ointments. This may be of practical significance if hydrocortisone free alcohol becomes available.

COUNCIL ON MEDICAL SERVICE

The Council on Medical Service has prepared the following review of the Research Council's study because of the widespread interest in data concerning prolonged illness.

SURVEY OF PROLONGED NONOCCUPATIONAL ILLNESS BY RESEARCH COUNCIL FOR ECONOMIC SECURITY

This study is based on the hypothesis, as set forth by the Research Council for Economic Security, Chicago, that whenever and wherever illness strikes, it is costly.[1] When the illness is serious and endures for months or, for that matter, several weeks, it can be catastrophic economically for the person and his family. How frequently such prolonged illnesses occur, how many people are affected, how great the financial cost is, and how well the cost is being met are part of the data that are not available. Nevertheless, the presumed frequency and extent of prolonged illness have been and are being used in arguments both for and against such proposals as the extension of employee benefit plans, compulsory sickness compensation, and national health insurance. Facts are essential for the discussion and development of these programs and for the consideration of alternatives.

This is the first of several surveys that the research council has under consideration, and it will be confined to prolonged nonoccupational illnesses among employed persons. The council has as its ultimate expectancy comparable studies of related areas, such as dependents, the aged, and the self-employed. The current study covers a vital segment of the population, namely, the wage earner.

The objective of this survey is to establish ". . . the relation of the incidence and duration of prolonged illness to: (1) the different occupational groups; (2) the different income groups; (3) age; (4) sex; (5) the various types of employee benefit plans and the coverages or services available under these plans; (6) the medical facilities and health services within the employing establishment; (7) the availability and use of medical facilities in the community."

BASIS OF STUDY

This study is confined to all employed persons with so-called "prolonged illness," i. e., nonoccupational disabilities (sickness and accidents) that cause absences from work for more than four weeks. Sickness within the meaning of this study is defined as both nonoccupational illnesses and injuries not covered under workmen's compensation; normal pregnancy cases are not included. Any abnormality or complication that requires special medical care and absence from employment will be treated as an illness and will be included in this survey.

When completed, the study will cover the experiences of 400,000 employees, or 1% of all private nonagricultural employment (total—39,404,000).[2] Quotas have been assigned to each of the nine census regions, including metropolitan, urban, and semirural communities, and to industries classified as (1) mining, (2) construction, (3) manufacturing, (4) transportation and public utilities, (5) trade, (6) finance, and (7) service. Occupational classifications include (1) managerial and supervisory, (2) clerical, sales and kindred workers, (3) skilled, and (4) semiskilled and unskilled.

FACT-FINDING PROCEDURES AND EXHIBITS

This survey is a continuous study, "recording experience at the time an illness is terminated, during the course of a 12 month period. Negotiations must be carried on separately with each participating company to arrange for the installation of the study, the setting up of the procedures and for the training of personnel."

Incident to the survey requirements that data are to be assembled on a current basis and that a running record is to be kept for 12 months, four separate work sheets have been set up and identified as schedules A, B, C, and D. The first three schedules are prepared from company records, and the fourth is designed as an employee questionnaire.

Schedule A is a quarterly report to the council and includes (1) number of employees, (2) number of employees absent because of illness, (3) breakdown of absences because of illness, and (4) number of days absent. Schedule B is a report that will be made only once giving details of the medical care program, such as (1) medical personnel, (2) diagnostic aids, (3) medical service, and (4) outside arrangements including any formal arrangements that either supplement or are in lieu of company's own facilities and that are being used for the care of nonoccupational illnesses of employees, and details of the employee benefit plan provisions for (1) hospitalization, (2) surgical care, (3) medical care, (4) sickness compensation, and (5) paid sick leave. Schedule C is a quarterly report to council and includes (1) personal data, (2) a chronological record of the illness, (3) nature of the illness or accident, and (4) medical costs and group plan benefits. Schedule D is an employee questionnaire that covers information not usually available in company or claim record files. Such data are medical insurance in addition to the group plan at the company, source of funds to help pay for cost of illness, and type and cost of medical aid, including physician, nurse, prescriptions, and special equipment.

The scope of this survey anticipates the accumulation of a large volume of case material and a vast number of statistical correlations. The final result should, however, establish a valid base on which to evaluate the medical, social, and economic implications from prolonged nonoccupational illnesses among employed persons.

FIRST PROGRESS REPORT

The council reports that as of the middle of May, 1953, arrangements were completed for reports to be submitted covering the experience of some 202,000 employees (approximately 50% of the total quota).

The following statistical results are based on assembled data covering a continuous three month period for a total of 39,675 employees. Whether or not ratios resulting from statistical correlations of one-tenth of the total number to be studied are sufficiently valid to establish trends is a question that must be deferred. This small group does not represent a cross section of the full sample, and many of the resulting ratios may change completely when the experiences are recorded for a full 12 month period and when the data for the full sample of 400,000 persons are assembled.

A review of the number of absences showed that there were nine prolonged absences per 1,000 employees: If this were projected for the 12 month period, there would be 36 prolonged absences in that period. The council suggests that preliminary investigations indicate a projection of 40 or more prolonged absences per year. Whereas it was expected that the absenteeism rate among women would be considerably higher than among men, there were no marked differences in the ratios; in fact, the absentee incidence among women was slightly lower. Although the absenteeism rate for women may be higher for illnesses of short duration, it apparently may not be so with respect to prolonged illnesses. There was a wide variation between the absences of male supervisors and those

COUNCIL ON MEDICAL SERVICE

The Council on Medical Service has prepared the following review of the Research Council's study because of the widespread interest in data concerning prolonged illness.

SURVEY OF PROLONGED NONOCCUPATIONAL ILLNESS BY RESEARCH COUNCIL FOR ECONOMIC SECURITY

This study is based on the hypothesis, as set forth by the Research Council for Economic Security, Chicago, that whenever and wherever illness strikes, it is costly.[1] When the illness is serious and endures for months or, for that matter, several weeks, it can be catastrophic economically for the person and his family. How frequently such prolonged illnesses occur, how many people are affected, how great the financial cost is, and how well the cost is being met are part of the data that are not available. Nevertheless, the presumed frequency and extent of prolonged illness have been and are being used in arguments both for and against such proposals as the extension of employee benefit plans, compulsory sickness compensation, and national health insurance. Facts are essential for the discussion and development of these programs and for the consideration of alternatives.

This is the first of several surveys that the research council has under consideration, and it will be confined to prolonged nonoccupational illnesses among employed persons. The council has as its ultimate expectancy comparable studies of related areas, such as dependents, the aged, and the self-employed. The current study covers a vital segment of the population, namely, the wage earner.

The objective of this survey is to establish ". . . the relation of the incidence and duration of prolonged illness to: (1) the different occupational groups; (2) the different income groups; (3) age; (4) sex; (5) the various types of employee benefit plans and the coverages or services available under these plans; (6) the medical facilities and health services within the employing establishment; (7) the availability and use of medical facilities in the community."

BASIS OF STUDY

This study is confined to all employed persons with so-called "prolonged illness," i. e., nonoccupational disabilities (sickness and accidents) that cause absences from work for more than four weeks. Sickness within the meaning of this study is defined as both nonoccupational illnesses and injuries not covered under workmen's compensation; normal pregnancy cases are not included. Any abnormality or complication that requires special medical care and absence from employment will be treated as an illness and will be included in this survey.

When completed, the study will cover the experiences of 400,000 employees, or 1% of all private nonagricultural employment (total—39,404,000).[2] Quotas have been assigned to each of the nine census regions, including metropolitan, urban, and semirural communities, and to industries classified as (1) mining, (2) construction, (3) manufacturing, (4) transportation and public utilities, (5) trade, (6) finance, and (7) service. Occupational classifications include (1) managerial and supervisory, (2) clerical, sales and kindred workers, (3) skilled, and (4) semiskilled and unskilled.

FACT-FINDING PROCEDURES AND EXHIBITS

This survey is a continuous study, "recording experience at the time an illness is terminated, during the course of a 12 month period. Negotiations must be carried on separately with each participating company to arrange for the installation of the study, the setting up of the procedures and for the training of personnel."

Incident to the survey requirements that data are to be assembled on a current basis and that a running record is to be kept for 12 months, four separate work sheets have been set up and identified as schedules A, B, C, and D. The first three schedules are prepared from company records, and the fourth is designed as an employee questionnaire.

Schedule A is a quarterly report to the council and includes (1) number of employees, (2) number of employees absent because of illness, (3) breakdown of absences because of illness, and (4) number of days absent. Schedule B is a report that will be made only once giving details of the medical care program, such as (1) medical personnel, (2) diagnostic aids, (3) medical service, and (4) outside arrangements including any formal arrangements that either supplement or are in lieu of company's own facilities and that are being used for the care of nonoccupational illnesses of employees, and details of the employee benefit plan provisions for (1) hospitalization, (2) surgical care, (3) medical care, (4) sickness compensation, and (5) paid sick leave. Schedule C is a quarterly report to council and includes (1) personal data, (2) a chronological record of the illness, (3) nature of the illness or accident, and (4) medical costs and group plan benefits. Schedule D is an employee questionnaire that covers information not usually available in company or claim record files. Such data are medical insurance in addition to the group plan at the company, source of funds to help pay for cost of illness, and type and cost of medical aid, including physician, nurse, prescriptions, and special equipment.

The scope of this survey anticipates the accumulation of a large volume of case material and a vast number of statistical correlations. The final result should, however, establish a valid base on which to evaluate the medical, social, and economic implications from prolonged nonoccupational illnesses among employed persons.

FIRST PROGRESS REPORT

The council reports that as of the middle of May, 1953, arrangements were completed for reports to be submitted covering the experience of some 202,000 employees (approximately 50% of the total quota).

The following statistical results are based on assembled data covering a continuous three month period for a total of 39,675 employees. Whether or not ratios resulting from statistical correlations of one-tenth of the total number to be studied are sufficiently valid to establish trends is a question that must be deferred. This small group does not represent a cross section of the full sample, and many of the resulting ratios may change completely when the experiences are recorded for a full 12 month period and when the data for the full sample of 400,000 persons are assembled.

A review of the number of absences showed that there were nine prolonged absences per 1,000 employees: If this were projected for the 12 month period, there would be 36 prolonged absences in that period. The council suggests that preliminary investigations indicate a projection of 40 or more prolonged absences per year. Whereas it was expected that the absenteeism rate among women would be considerably higher than among men, there were no marked differences in the ratios; in fact, the absentee incidence among women was slightly lower. Although the absenteeism rate for women may be higher for illnesses of short duration, it apparently may not be so with respect to prolonged illnesses. There was a wide variation between the absences of male supervisors and those of male skilled workers, although there is some doubt as to the validity of the figures for supervisors. The number of prolonged absences for the supervisors is under "2" while for the skilled worker it was "15." These figures suggest that the skilled worker group may constitute a special problem area and that a special investigation may be necessary. "The nine absences represented a loss of 460 actual work days per 1,000 employees. This is equivalent to the loss of seven people full time for the three months period. The 460 days represent an average loss among the employees who were ill of 10 weeks of work (assuming a normal five-day work week)."

[2] Employees in Non-Agricultural Establishments, January, 1952, United States Department of Labor, Bureau of Labor Statistics, United States Government Printing Office, 1952. Government establishments have been excluded from total.

There were insufficient data on absences of less than one week to include the factor of the relation of prolonged absences to all absences in this report. Accordingly, comparisons were made between absences of one week or more and prolonged illnesses. Among all the workers covered in this report, 20% of all recorded absences of one week or more were prolonged illnesses. Here again women have an absence figure lower than the men, less than 15% compared to over 20%, respectively. "That the prolonged illnesses among skilled workers may present a special problem is re-emphasized. All of the other occupational groups are at or below the percentage for the whole group (20%) whereas the skilled worker showed an index figure of 48%."

The reversal of the incidence of absenteeism among female workers compared to male workers approaches confirmation in this group. Among male workers, prolonged illness accounted for 22% of all the absences; among the female workers, prolonged illness represented 13.4% of the absences. The research council suggests that, if prolonged illnesses represent 20% of all absences of one week or more, it is an important problem and that it becomes one of serious concern when it is noted that the prolonged illnesses were responsible for 56% of all the time lost during these absences.

Absences of not more than eight weeks represented 60% of the total absences but caused only 34% of the total time lost. Illnesses causing absences of more than 13 weeks, representing 20% of the illnesses, accounted for 46% of all time lost. The average duration of the prolonged illnesses (250 cases) was 51.18 days. While 250 illnesses are insufficient for any conclusions, they may be a clue. The duration figure is important in determining proper insurance coverage.

"Male and female workers were responsible for the same share of the prolonged illnesses as their percentage of the total number of employees. Clerical workers representing 17 per cent of all workers reported accounted for 11.45 per cent of all prolonged illnesses; an index figure of 33. Again male skilled workers representing less than 13 per cent of the workers reported accounted for 21 per cent of all of the prolonged illnesses; an index figure of 65."

The following ratios are based on 335 cases in which there was absence of more than four weeks. Some of the more obvious causes of prolonged illnesses were heart disease, nervous and mental disease, and chronic arthritis and rheumatism. It is interesting to note that, among the employees covered in this report, the largest percentage of cases were caused by diseases of the digestive system (29% of all cases). Diseases of the respiratory system caused 14.1%; fractures of the skull, spine, ribs, or limbs, 8.1%; malignant and benign neoplasms, 5.1%; and arthritis and rheumatism, except rheumatic fever, 4.8%. While diseases of the digestive system and respiratory tract were highest in terms of frequency, they were lowest in mean duration in weeks, 8.2 weeks and 7.7 weeks, respectively. Neoplasms and arthritis and rheumatism, which reflected the lowest percentage in frequency, were among the highest in terms of mean duration, 11.8 weeks and 13.6 weeks, respectively.

The data of the distribution of illnesses by age groups are, we believe, of sufficient interest to show that part of the chart reflecting "all illnesses" without any detailed consideration to that part of the chart breaking down the age groups according to disease.

Age Group	Number of Persons	%
24 and under	22	6.6
25-34	65	19.4
35-44	79	23.6
45-54	74	22.1
55-64	84	25.1
65 and over	11	3.2

There is only a 1.5 percentage point differential between the 35 to 44 age group and the 45 to 54 age group; the higher count is accounted for by the younger age group. With the exception of the group 24 years and under and the group 65 and over, the percentage point differential is not dramatic. If the preliminary ratio of 3.2% for the age group 65 and over is at all typical rather than atypical, prolonged illness may no longer be considered as being primarily a problem of geriatrics. "In only two of the disease groups did the workers over 45 account for more than one-half of the cases."
